PSEUDOMALIGNANT AND PRECANCEROUS LESIONS OF THE CERVIX

EMIL NOVAK, M.D.
BALTIMORE

In almost every statistical study of cancer results that has ever been made, the one conclusion which is always stressed is that the factor which, far more frequently than any other, determines the fate of the patient is the stage at which proper treatment is instituted. On this conclusion are based all the campaigns of public instruction. In the treatment of cancer of the cervix the profession seems to have reached an essential impasse with our present-day methods in spite of the fact that improvements and refinements in radiotherapy are still being pushed, with rather unimpressive improvements in results here and there. For the present, therefore, the obvious point of attack in the cancer campaign lies in the effort to increase the proportion of the early cases in which treatment gives such a worth while chance for cure.

Except for the occasional "accidental" find, one cannot be expected to discover the early cases of cancer unless patients are educated to seek advice as soon as suspicious symptoms appear, though even then, unfortunately, the patient is in some cases already doomed. On the other hand, physicians are not justified in placing the blame for delayed treatment entirely on the patients, for our own skirts are not by any means entirely clean. It is as unfortunate as it is true that there are still not a few patients who lose their opportunity for cure because of delay on the part of the physician, a delay not nearly so frequently due to lack of knowledge as to lack of thoroughness and conscientiousness.

What can physicians in general do to help the cause? They can contribute not only by educating the public collectively but also by taking advantage of everyday opportunities for advising individual women as to possible danger signals and the vital importance of heeding them. But they can do much more than this. They can develop in themselves habits of thoroughness and conscientiousness which will not permit them to omit painstaking examination of all cervixes that come under their observation, and especially those of patients with abnormal bleeding or other suspicious symptoms. And there is still more that they can do. They can learn to recognize lesions that are only suggestive of cancer or indicative of early stages of the disease, lesions quite different from the obvious late stages of cancer, such as the cauliflower growth or the excavated ulcer.

A great field for possible advance will be opened up when the general practitioner develops the habit of intensive study of the cervix by careful inspection rather than by mere casual palpation and when he appreciates that cancer may exist even though such an examination reveals only a slightly hardened and perhaps granular or slightly ulcerated area on the cervix, frequently bleeding on slight touch, or a spongy, slightly vegetative area on one or the other lip, with perhaps the same vascularity. If such an area is found, the existence or nonexistence of cancer can be definitely determined in practically every case, and here lies the final duty of the general practitioner; viz., to press the matter unremittingly to a decision, which may be so momentous to his patient. This will mean that both he and the patient must go to a little trouble.

The diagnosis will in such cases often mean biopsy and pathologic examination, so that the average physician will probably elect to put the burden on the gynecologist, presumably trained in such procedures. Since physicians are, after all, primarily people and therefore not always amenable to exhortation and the dictates of conscience, it is obvious that the right plan of procedure cannot be made the universal one. Nevertheless, in his concern at the easily understandable indifference of the public, the physician should not close his eyes to the less forgivable apathy often noted within his own ranks.

The particular problem to be considered in this paper, however, concerns the specialist—the gynecologist and the pathologist—even more than the general practitioner, for it deals with what may be called the earliest stages of cancer and with lesions that in some respects resemble cancer and in others do not, as well as with still other lesions which are commonly looked on as predisposing to cancer.

The term "precancerous" has been used for many years in different senses by different writers and with differing degrees of enthusiasm. By one group the designation has been applied rather generally to lesions believed to predispose to cancer and embracing especially chronic irritative and inflammatory conditions, even though these in themselves are very frankly benign. The other and better definition of the term precancerous refers to lesions that exhibit cell activity unusual in benign conditions and yet lack certain characteristics of actual cancer. When used in this sense, the term conveys the impression that the lesion in question is, from a histologic standpoint, a transitional one, the natural corollary being that it represents a real stepping stone between the benign and the malignant.

Up to comparatively recent years such a concept of the term produced some resentment among a great many pathologists, because of the belief that a lesion is either benign or malignant, though in some cases there may be difficulty in making the histologic differ-

Read before the Section on Gynecology and Obstetrics at the annual meeting of the Michigan State Medical Society, Detroit, Sept. 24, 1936.

entiation between the two. During the past few years, considerable evidence is accumulating to suggest, though not perhaps to prove, that there is actually a very gradual histologic transition from the benign to the malignant and that certain so-called borderline conditions may actually represent transitions to cancer or very early forms of the disease, even though there is no

Fig. 1.—Squamous epithelium creeping in long columns beneath the columnar gland epithelium, often proliferating so as to blot out the latter and form large epithelial nests, which may be mistaken for cancer.

morphologic criterion to determine just when the definitive stimulus is applied that sets the cells off on a malignant career.

In whichever of the two foregoing senses the term precancerous is used, I believe it has served a useful purpose, keeping before the physician the idea of lesions precursory to actual cancer but clinically benign in themselves, so that their removal gives a measure of protection against cancer. It need hardly be emphasized that most lesions of this sort are merely predisposing and that their unfavorable tendencies can lead to cancer only when some other constitutional factor, as yet unknown, is operative. The profession is as yet totally in the dark as to the exciting cause or causes of the whole group of cancer diseases and so can do nothing to avert or counteract these unknown forces. But it can readily correct most of the benign irritative lesions, which by almost unanimous consent have an influence on the development of cancer; and this represents about the sum total of cancer prophylaxis at the present day.

A number of studies of large series of cases have been made on this point (Pemberton, Smith and his associates, Bland, and Graves) and these have been summated by Saltzstein and Topcik.¹ Of 18,562 patients who may be considered to have had adequate treatment for cervical irritative lesions, only fifteen were known to have developed cancer later. On the other hand, of 2,255 patients who actually had cervical cancer, only thirty-three had had adequate treatment of preexisting cervical lesions.

In no field are the precancerous lesions more interestingly illustrated than in the cervix. Here is encountered one of the most common types of cancer, and here, chiefly as a result of childbirth trauma, is found an unusual incidence of chronic irritative lesions, in a

part of the uterus which is readily accessible to both diagnostic and therapeutic procedures. The body of the uterus, on the other hand, is relatively free from the traumatic effects of childbirth, and there is much doubt whether the presence of myomas influences the incidence of corporeal carcinoma to any noteworthy degree. On the other hand, it is here that the ovarian hormones exert their outstanding effects, and the work of the past two years has shown a rather remarkable relationship between these hormones and carcinogenesis, as I shall later discuss. Here, then, is a possible predisposing factor to be considered in connection with the genesis of corporeal cancer, and one which I do not believe can be disregarded.

Starting with lesions of the cervix that are frankly benign, and which from the standpoint of cancer are merely predisposing but not precancerous, by far the most important group is that represented by the chronic inflammatory and irritative lesions so very frequent in this portion of the uterus. Even in the most intense forms of chronic cervicitis there is usually not the slightest pathologic simulation of cancer, although in not a few there is much justification for clinical suspicion. One frequently sees cervixes that are badly eroded, irregularly hypertrophied and indurated, with a granular mucosa which bleeds very readily on slight touch and in which, therefore the clinician would be very remiss if he did not at least suspect the possibility of a malignant condition. And yet in such cases one often finds, in spite of extensive inflammatory changes, not the slightest suspicion of histologic malignancy if a biopsy is done, as it should be. On the other hand, in lesions which clinically are far less conspicuous and which must be searched for much more intensively, one may find definite evidence of cancer.

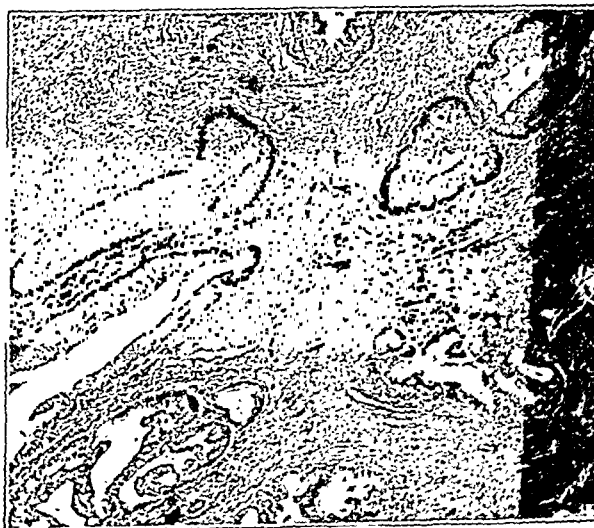

Fig. 2.—Large epithelial nests seen with epidermidization of cervix but with none of the cytologic changes seen with cancer. Compare with figure 3.

In a rather considerable proportion of inflammatory lesions, as well as in not a few cervical polypi, one may encounter histologic pictures which, while entirely benign, may easily be mistaken for cancer unless one is familiar with their characteristics and significance. The changes to which I particularly refer are those designated as squamous metaplasia or epidermidization. In this condition columns and nests of squamous epithelium may invade far below the surface, so that in

1. Saltzstein, H. C., and Topcik, H. C.: *Am. J. Cancer* 17: 951-961 (April) 1933.

marked cases a pattern is produced which is not unlike that of epidermoid cancer. Much more frequently one sees that the squamous invasion proceeds from the basal layers of the surface mucosa, which flows down along the gland wall beneath the cylindric epithelium. The proliferation of the squamous epithelium may produce flattening or disappearance of the columnar gland cells and eventually replacement of the gland by a column of squamous epithelium. In such cases the cervical stroma may show numerous nests of squamous epithelium and hence the simulation of cancer.

The distinction is usually easily made, chiefly on the following points: 1. The invading epithelium shows no sign of anaplastic activity, though even this may in some areas be simulated, as when the section passes tangentially through the basal layers, which normally show more compactness, larger and heavier staining nuclei, with perhaps occasional mitosis. Examination of other fields, however, will almost always clear up this point of doubt. 2. Characteristically the invading squamous epithelium follows the scaffolding of the glands, creeping beneath the glandular epithelium as a column of from one to many cells in thickness, which by further proliferation encroaches more and more on the gland epithelium and often blots it out almost or quite completely. One then has the picture of solid nests and columns of cells deep in the stroma, and in this respect resembling a carcinoma. It is rare, however, not to find the telltale transition phases showing the manner of development of these extreme pictures.

Even in cell nests which at first sight look quite solid, one often sees fenestrae of mucoid content, degenerated remnants of the original mucoid cylindric cervical gland epithelium. The manner of production of this type of epidermization, as well as the difference between its histologic appearance and that of genuine cancer, are well shown in figures 1, 2 and 3. For a fuller discussion of the histogenesis of this interesting process I refer to a previous paper of my own.² The lesion is one of great frequency and of great importance from the standpoint of differential diagnosis, and mistakes are still frequently made, though less often than formerly.

To pass on to the discussion of lesions which are precancerous in the sense of being possible precursors of the disease rather than merely predisposing factors in its development, especial interest attaches to leukoplakia, which up to a few years ago was practically an unheard of lesion so far as the cervix is concerned. The present-day interest in this condition is due to the development of two new diagnostic methods, the colposcope of Hinselmann and the Schiller tinctorial test. During the past ten years or so Hinselmann³ has published numerous papers stressing the fact that only with the magnifying colposcope can one hope to discover the often tiny areas of leukoplakia. More important, however, is his contention that cervical leukoplakia in general must be looked on as a precursor of cancer, a view which, as will be seen, has led to widespread discussion and much difference of opinion.

The Schiller test,⁴ based on the discovery by Lahm that the normal squamous epithelium of the portio is rich in glycogen while cancerous epithelium is lacking in glycogen, has also been the subject of much discussion. The method is often though not necessarily

combined with colposcopy. The procedure consists of painting the cervix very thoroughly with Gram's solution (1 part of iodine, 2 parts of potassium iodide, 300 parts of water), this giving better results than compound solution of iodine, which is used by some. Instead of painting the cervix, one may spray the solution on with an atomizer, as Henriksen⁵ has suggested.

The normal squamous epithelium of the cervix takes a deep brown or mahogany stain, while cancerous epithelium remains unstained. The problem, however, is not quite so simple as this, chiefly because other lesions than cancer may fail to take the stain. This applies especially to the leukoplakic group. Moreover, it should be remembered that the cylindric epithelium of the cervical canal takes only a rather light pinkish brown stain, and proper cognizance of this must be taken in the numerous cases in which erosions and ectropion are associated features. Traumatic abrasion of the squamous epithelium may also interfere with its tinc-

Fig. 3.—The cell nests of genuine early cancer, made up of highly anaplastic epithelium.

torial response, while cancers in which ulceration and necrosis have developed may take a dirty brownish stain, though at their growing margin whitish unstained areas may be noted.

So far as these two diagnostic procedures are concerned, my own impression, after some experience with both, is that they are of rather limited value. Neither procedure is of the kind which can be expected to achieve adoption by the general profession, nor is this desirable. Considerable experience is necessary for proper interpretation with either method, and neither is of much value unless combined with biopsy and pathologic diagnosis, so that it is quite certain that the general practitioner will wish to transfer this responsibility to the specialist who is trained in such matters. Colposcopy, moreover, is a time-consuming procedure.

The chief value of the Schiller test, even to the expert gynecologist, is to indicate the proper points for biopsy, though in the great majority of these cases the suspicious areas are apparent enough, sometimes

pathetically so. The same statement may be made concerning the colposcope, so far as actual cancer is concerned.

I do not believe that a good gynecologist who examines the cervix very carefully in a very good light will overlook many cancers that the colposcope would reveal, in spite of Hinselmann's contention to the contrary. Moreover, this procedure as well as the Schiller test, is obviously intended chiefly for the detection of the

Fig. 4.—Leukoplakia of the cervix, presenting as an unstained whitish plaque with the Schiller test, but pathologically showing only hyperkeratosis and slight increase of cell activity, with occasional mitoses but with no suggestion of malignancy.

earliest cases, those in which there has been no bleeding, for the occurrence of the latter presupposes that ulceration has already begun. To pick up these very early cases the colposcope would have to be used practically as a routine, which is almost out of the question in most clinics. In cases in which symptoms have already developed there is rarely any difficulty in finding the suspicious area with the naked eye.

On the other hand, both these procedures are of importance in that intensive study of the cervix which alone will ultimately throw light on the very earliest stages of cancer, as well as of those lesions which many look on as stepping stones to cancer. For this reason their employment in properly manned clinics is highly desirable, for they will keep constantly before the staff the importance of intensive study of the cervix, and their employment, combined with biopsy, should yield material for the study of a group of lesions concerning which pathologic knowledge is still anything but precise.

As a matter of fact, in many laboratories of gynecologic pathology the recently developed intensive interest in the cervix is already reflected in the increased amount of this borderline material. Up to the past few years there was only an exceptional case in which the presence or absence of a malignant condition could not be reported with reasonable certainty. The increased number of cases in which pathologists will disagree is due not only to the increased interest in biopsy, which has been engendered by the work of Hinselmann and Schiller, but also to the fact that there is no unanimity among pathologists as to the criteria of very early cancer.

Even in the clinically early cases with which physicians have had to deal in past years, the pathologic diagnosis has usually been easy enough, for such lesions present exactly the same pathologic features as do very late cancers. There is the same evidence of varying

degrees of cell anaplasia and the same evidence of invasiveness. The late cancers differ from the early ones only in degree and perhaps in such secondary changes as infection, necrosis and ulceration.

But there must be even earlier phases, phases that the physician has probably been overlooking. Is it not logical to believe that there must be stages before actual invasion sets in, in which the epithelium has nevertheless already embarked on its malignant career? As a matter of fact, it is around this point that much of the present-day discussion centers, some holding that evidence of invasiveness is a *sine qua non* to the diagnosis of a malignant condition, others that even without this there may be a reasonable certainty of one.

The various degrees of leukoplakia have furnished the basis for much of this discussion. The term is really a clinical rather than a pathologic one, and as employed by Hinselmann it is a very comprehensive term embracing many different degrees of abnormality. These range from simple hyperkeratosis with perhaps slight increase in activity of the basal layers (Hinselmann's rubric I) at one extreme to lesions which most pathologists would call cancer, characterized as they are by hyperchromatosis, mitosis and other evidences of anaplasia, together with budding into the underlying stroma (rubric IV).

Between the first two grades of the four described by Hinselmann (rubrics I and II) and actual cancer there is a wide gap, almost as wide as that between normal epithelium and cancer. And yet this author believes that all grades of leukoplakia are precancerous, a view which, to my mind, is not supported by his evidence. Only a very small group of cases have been discovered in which cancer appears to have developed on a leukoplakic basis. However, as Meyer⁶ says, this is no more justification for considering leukoplakia an important precancerous lesion than the occasional occur-

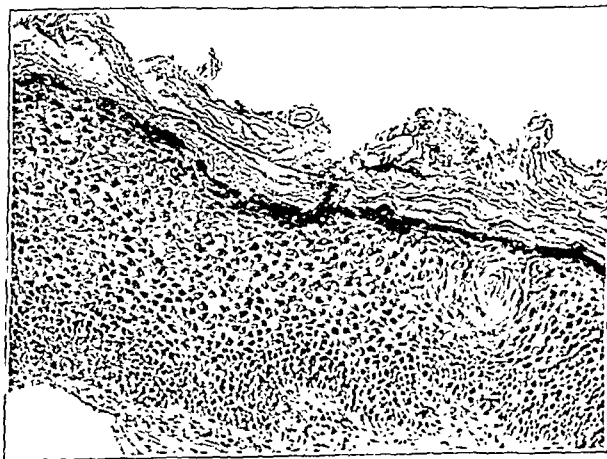

Fig. 5.—Intra-epithelial carcinoma, without invasiveness but with loss of normal stratification, hyperkeratosis, an attempt at pearl formation and definite anaplastic cell changes, with frequent mitosis. This picture is often spoken of as Bowen's disease of the cervix, from an assumed analogy with Bowen's disease of the skin.

rence of carcinomatous changes in polypi justifies the statement that polypi are precursors of cancer.

These simpler grades of leukoplakia are much more logically explained, it seems to me, as instances of the differentiation anomalies which are so commonly seen throughout the genital tract, as I have discussed in a

6. Meyer, R., in Henke, Friedrich, and Lubarsch, Otto: *Handbuch der speziellen pathologischen Anatomie und Histologie* 7:182, 1934.

previous paper.⁷ Patches of squamous epithelium may be found on the endometrium, and endometrial islands may be found in the tubal mucosa. Similarly it might be expected that in some cervixes one might find islands in which the epithelium is more highly differentiated than is normal for the region (prosoplasia), with hyperkeratosis as an evidence of this. A good analogy may be seen in the amniotic epithelium, which, like the skin, is of ectodermal origin. The so-called amniotic caruncles are plaques of skinlike appearance which may be found in the normally cuboidal epithelium of the amnion, representing just such a differentiation anomaly as I believe may occur in the case of leukoplakia of the cervix.

Between Hinselmann's rubric II and rubric III there is a very sharp gap, for in the latter one finds evidences of cell anaplasia quite like those of cancer, though invasiveness is lacking. It is this group in which we have been most interested in our own laboratory. In general, the picture corresponds to what many have called intra-epithelial carcinoma, carcinoma in situ, carcinoid, or Bowen's disease. In this condition the epithelium shows anaplastic changes quite comparable to those which are ordinarily associated with cancer, but there is no penetration through the basement membrane. It is significant that exactly the same picture of noninvasive epithelial carcinoma is often to be seen at the growing margin of very frank cancer.

The latter observation lends support to the view held by many that intra-epithelial carcinoma is genuine cancer, although the cells have not yet entered on the career of invasiveness which is the chief characteristic of cancer as one ordinarily sees it. From the relatively small amount of cervical material of this sort as yet available for study, it would seem that in this preinvasive stage the lesion is readily curable by very simple conservative measures. Moreover, there may apparently be a very definite and perhaps a long pause or lag between the intra-epithelial and the invasive phases of the process. This would seem likely if one harks back to the example of Bowen's disease of the skin,⁸ in which the lesion may be noninvasive for many years, with the development then of invasiveness and metastasis.

Intra-epithelial carcinoma of the type I have been describing is a rather rare lesion in the cervix, and the greatest caution is necessary in its diagnosis. The chief hazard comes from incompleteness of study, and I have on a number of occasions, in lesions at first thought to belong to this category, found on the study of other sections that actual cancer was present close by. In the study of all such early lesions the importance of numerous, preferably serial, sections cannot be too strongly emphasized.

No discussion of this general subject would be complete without stressing the value of biopsy. In many instances not even the most expert gynecologist can determine the presence or absence of cancer by clinical methods alone. Most cases of very early cancer are either accidental finds, perhaps in patients with no symptoms at all, or they are revealed by the careful investigation of cervixes that are regarded merely as suspicious. In some of these there is perhaps a leukoplakic area, but more often one's suspicions are aroused by a small area of induration with very slight surface ulceration, or a firm area of rather granular appearance that bleeds on slight touch, or a finely vegetative area

which likewise shows marked vascularity. It is such lesions as this for which one must search the cervix, and not merely the large excrescent cauliflower growths or the various indurated or ulcerative lesions that characterize the late lesion, where diagnosis is about as easy as the prognosis is unfavorable.

In these late stages the microscope could almost be dispensed with in diagnosis, but in the early group mentioned previously it is the final arbiter. Biopsy is here of crucial value, and it is essential that the tissue for examination be obtained directly from the area under suspicion. If this is not done the pathologic report is worse than useless, for a negative report will lull the clinician into a false security while a genuine cancerous lesion may be progressing a short, or perhaps a considerable, distance from the biopsy wound.

The pathologist can be expected to find cancer only if it is present in the tissue submitted to him for examination, so that the important responsibility of proper biopsy belongs to the clinician, who may employ any

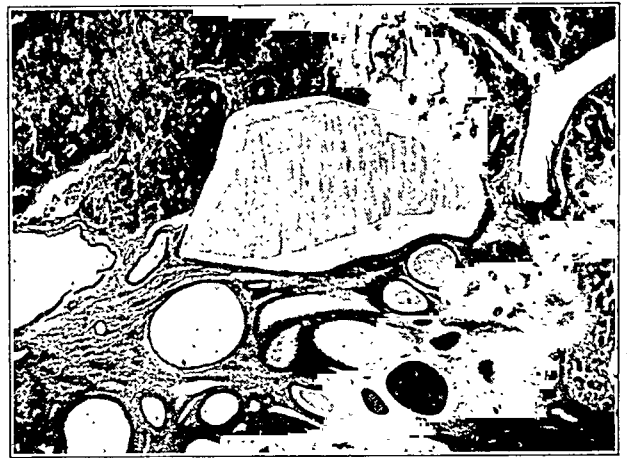

Fig. 6.—Adenocarcinoma of the uterus, with hyperplasia of endometrium adjoining it, in a patient aged 59.

one of several methods to obtain tissue from the cervix. When the latter is easily accessible I prefer a sharp scalpel, with cauterization of the wound edges with the electrocautery. When the cervix is high up and the vaginal canal is long and narrow, the scalpel is apt to be awkward and unsatisfactory, and in these the punch is a very satisfactory instrument for biopsy. Others prefer the cautery knife or the endothermy knife for this purpose, though, especially with the former, the tissue is apt to be partially cooked, so that the resulting sections may not be so satisfactory.

Little need be said as to the supposed dangers of biopsy, for, even though these were real, the procedure would still be justified because of the indispensability of the information that it yields and that can be obtained in no other way. As a matter of fact, there is no worth while evidence to indicate that biopsy of the cervix is fraught with any extra hazard to the patient.

One other point concerning the rôle of the pathologist is worthy of special stress. In dealing with very early lesions it should be borne in mind that evidence of cancer may be lacking in one part of the biopsy tissue and be present in another, so that serial section is of great importance. The entire block should be sectioned, and sections at various levels should be stained and examined so that nothing of importance will be overlooked. I have more than once been inclined to the

7. Novak, Emil: *Am. J. Obst. & Gynec.* 24: 635-655 (Nov.) 1932.
8. Bowen, J. T.: *J. Cutan. Dis.* 30: 241-255, 1912.

diagnosis of precancerous lesions, such as Bowen's disease or intra-epithelial noninvasive carcinoma, only to find in other sections *indubitable evidence of invasive carcinoma*.

In this connection I have in a recent paper called attention to the frequent advisability, more especially in women beyond the child-bearing period, of cervical amputation rather than mere biopsy when there is a suspicion of an early malignant condition. By this plan the whole cervix is made available for complete pathologic study. If cancer is revealed, the appropriate radiotherapeutic measures can be instituted; if not, the procedure may be considered to have carried with it a considerable measure of prophylactic value.

PRECANCEROUS LESIONS OF THE CORPUS UTERI

Aside from the very doubtful rôle of myomas in predisposing to endometrial carcinoma, there has been little discussion as to lesions that might be considered as precancerous in this portion of the uterus. Within the past few years, however, considerable evidence has accumulated to indicate that estrogenic substances may exert a markedly carcinogenic tendency, particularly in those organs which, like the breast and the uterus, are normally under the physiologic control of these estrogenic principles.⁹ This evidence has been summarized in a recent paper by Yue and myself,¹⁰ based on the study of 864 cases of hyperplasia of the endometrium and 104 cases of adenocarcinoma of the uterine body.

The accepted cause of hyperplasia is a persisting hyperestrinism, so that it seemed of interest to determine whether there is any relation between this lesion and adenocarcinoma. Without going into details, I may say that no such relation is demonstrable during the reproductive epoch, when corporeal carcinoma is relatively infrequent and hyperplasia very common. On the other hand, in a surprising proportion of cases of women well beyond the menopause, hyperplasia and adenocarcinoma were found to coexist in one and the same uterus.

That hyperplasia may occur long after the menopause has been shown not only by our own studies but also by those of others (Breipohl, Schröder), though one can only speculate as to the source of the estrogenic stimulation at this period of life, when the ovaries have presumably lost their internal secretory function. But when the endometrium of the postmenopausal woman is subjected to prolonged and persistent estrogenic stimulation, not only is hyperplasia produced but there is apparently a strong tendency to the development of actual cancer. In fully twenty-five of our cases, for example, such pictures as that shown in figure 6 are found, with hyperplasia and carcinoma existing side by side and often with transition pictures between the two lesions.

This is not to say that the hormone stimulus actually produces the cancer, the suggestion rather being that an abnormal estrogenic stimulus acting on a tissue which by age and other unknown factors is rendered prone to cancer development exerts a strong predisposing influence, perhaps just as does any form of chronic irritation. In view of recent studies showing the close relationship of estrogenic and carcinogenic substances and the reports of the actual production of what is apparently genuine carcinoma by the injection of estrogenic principles, it is not impossible that the relation

between the hormone-produced hyperplasia and cancer is a much more direct one, though present knowledge does not warrant such a conclusion. For a fuller discussion of this problem, however, I may refer the reader to our recent paper on the subject.

SUMMARY

For the present, the most promising line of advance in the cancer campaign is the effort to increase the proportion of early cases submitted to proper treatment. Important though popular education unquestionably is, there is still a great opportunity for education within our own ranks, along lines which have been indicated in this paper.

The term "early cancer" is a very relative one, and the lesions that I have discussed have been chiefly the earliest phases of the disease, as well as certain lesions which histologically are of a borderline type. Diagnosis in this group concerns the gynecologic specialist and the pathologist much more than the general practitioner, though the latter should train himself to recognize merely suspicious lesions as well as those characterizing actual cancer.

Recent intensive studies on the cervix have focused attention on leukoplakia as a possible precursor of cancer. The term is a rather broad one, embracing various degrees of hyperkeratosis, increased cell activity and even anaplasia. In many cases there is no histologic suggestion of a malignant condition, and the evidence that such lesions are important precursors of cancer is very unconvincing. In the leukoplakia group, however, many include also lesions in which the epithelial anaplasia is indistinguishable from that of cancer, though there is no invasiveness. Do these cases of carcinoma in situ, carcinoid, intra-epithelial cancer or Bowen's disease of the cervix represent preinvasive phases of genuine carcinoma? I believe that they do, though a long interval may elapse before the second and more decisive phase of malignancy, the invasiveness, may manifest itself.

The evidence is quite convincing that cancer is preceded by a preinvasive stage, but there is still much doubt as to whether the reverse is true; that is, whether the so-called preinvasive stage inevitably becomes cancer. The pathologic feature that determines clinical malignancy is invasiveness, and hence on this point I do not agree with Schiller, who does not hesitate to diagnose cancer even in the absence of invasiveness, although he concedes that even many years may elapse before invasiveness may—or may not—develop. But during this preinvasive stage the lesion is still clinically a benign one and hence should be considered a precursor of cancer rather than an early stage of the latter. If Schiller's concept is true, the life history of cancer of the cervix might be of many years' duration, the traditional invasive phase being merely a terminal one. During the preinvasive stage the lesion might be a practically invisible one, with no tendency to metastasis at this stage, during which it can be cured by simple conservative procedures. But malignancy is, after all, a clinical and not a pathologic attribute, and it would seem paradoxical to apply the term cancer to lesions in this preinvasive stage. Something else is necessary before they can actually become clinically malignant, and the pathologic evidence that this final decisive step has been taken is furnished by the microscopic demonstration of invasiveness.

In the study of borderline cases and in the search for very early cancer, the colposcope and the Schiller tinc-

torial test are of considerable value; but they are handicapped by various limitations, which have prevented their more general adoption. Both methods, however, are valuable assets in any clinic, because they stimulate an interest in intensive study of the cervix and also unquestionably help in the recognition of precancerous lesions and occasionally of early cancer itself.

So far as precancerous lesions of the uterine body are concerned, attention has been called to the not uncommon observation of hyperplasia long after the menopause and the not infrequent coexistence of hyperplasia and adenocarcinoma in postmenopausal women. This suggests that postmenopausal hyperestrinism, whatever its cause may be, may be a precancerous factor of some importance.

THE USE OF STAPHYLOCOCCUS TOXOID IN THE TREATMENT OF CHRONIC OSTEOMYELITIS

JOSEPH BUCHMAN, M.D.

NEW YORK

On the wings of the now classic tragedy of Bundaberg, Australia,¹ came a new method of approach in the therapy of staphylococcal infections. The immediate subsequent investigations by Burnet and his associates,² and those of Dolman,³ Pantón, Valentine and Dix,⁴ Parish and Clark⁵ and others have enriched our knowledge of the immunology of staphylococcal infections with special reference to their toxins, toxoids and antitoxins. These workers demonstrated that active immunization can be induced by the administration of staphylococcus toxin. They furthermore developed staphylococcus toxoid, which is staphylococcus toxin detoxified with formaldehyde, capable of bringing about similar responses in the living animal without the limitations and dangers incidental to the use of toxin. This induced active immunity has in some instances been sufficient to enable rabbits to withstand injections of definitely lethal doses of living toxigenic staphylococci or staphylococcus toxin. Dolman⁶ carried this work further by demonstrating the antigenicity of toxoid in a series of six normal human volunteers.

In view of these experimental demonstrations of active immunization of animals and human beings it appears theoretically possible to attack staphylococcal infection by means of subcutaneous administration of toxoid. Dolman⁶ concluded that toxoid therapy "might result in a favorable modification, and perhaps cure . . . with some degree of protection against similar infections in the future." To Holman⁷ it seemed "a perfectly logical procedure to build up antitoxin [by

the use of toxoid] as a defense mechanism if it is reasonably certain that no abnormal or harmful sensitization will later result."

The therapeutic application of staphylococcus toxoid has been carried out by a number of investigators.⁸ With a few exceptions their efforts have been largely confined to superficial staphylococcal infections and the reported results have in general been decidedly favorable. Cures were reported and recurrences, when they occurred, were often milder than the original infections. The enthusiasm of several authors led them to the belief that toxoid therapy is far superior to any other method of treatment in superficial staphylococcal infections. In contrast to these favorable reports are the unsatisfactory experiences of Kindel and Costello⁹ and Cornbleet and Rattner.¹⁰ Dolman¹¹ attributed their unfavorable results to the use of a monovalent toxoid and pointed to the importance of using a polyvalent preparation from several highly toxigenic strains of staphylococci.

The therapeutic application of toxoid in fifty-nine cases of chronic and subacute staphylococcal osteomyelitis was recently reported by Dolman.¹² Though he recognized the special difficulties confronted in the evaluation of any method of therapy in chronic osteomyelitis, he nevertheless reached the conclusion that, "despite all these difficulties, distinctly favorable results appear in general to attend the use of staphylococcus toxoid in chronic osteomyelitis." Ramon and his collaborators^{8h} have very recently reported "encouraging" results in cases of osteomyelitis under toxoid therapy. They felt, however, that their experience was too short to warrant the final judgment of the therapeutic value of toxoid in this type of case.

Experiences at the Hospital for Joint Diseases have led me to believe that with thorough surgery followed by maggot therapy we can in a high percentage of suitable cases bring about a local healing of such a nature that relighting of the processes at the treated sites will in all probability not occur. This belief is based on the character of the healing that takes place, which I have described elsewhere.¹³ In view of our

experiences with local therapy and in view of the promising reports of the immunologic therapy previously described we were fired with the hope of being able (1) to immunize these unfortunate patients against future exacerbations of old lesions, (2) to prevent new metastatic lesions in bone and soft tissues and (3) to expedite the healing of existing lesions.

CLINICAL MATERIAL

With these ideas in mind, we began in the latter part of December 1934 to administer staphylococcus toxoid in a group of unselected cases of chronic staphylococcal

osteomyelitis. This group consisted of thirty-eight patients ranging in age at the time of observation from 7 to 55 years, as shown in table 1. The duration of the disease varied from two months to fifty-four years before the onset of toxoid therapy, with more than half of the cases lasting six years or less (table 2).

Only a few of these patients had only one prior operation. The remainder had had many operative procedures; one patient had as many as twenty-two on one tibia over a period of eighteen years without ever obtaining even a temporary closure of the wound. Thirty of these cases were of hematogenous origin, four were the result of compound fractures, one was subsequent to an infection following an open operation performed elsewhere for a simple dislocation of an astragalus, two were the result of secondary infections following operations for tuberculous knees, and one was subsequent to an open operation for nonunion of a fracture in a syphilitic patient with tabes dorsalis. The etiologic agent in all cases was proved to be *Staphylococcus aureus*. The status of the patients at the beginning of toxoid therapy is shown in table 3.

All these patients, save for a few exceptions, had previously been operated on elsewhere and had various types of after-care including the classic Carrel-Dakin and Orr methods. These cases, which presented ulcers, had previously had pinch grafts or skin plastic operations with or without temporary healing.

SURGICAL THERAPY

During the course of the toxoid therapy those cases presenting frank bone lesions were subjected to radical saucerization operations when anatomic topography permitted. The great majority of these patients were

subsequently treated with maggots. A few of these were treated with "maggot enzyme, Lederle,"^{12a} and several were treated with allantoin supplied by the Bureau of Entomology of the U. S. Department of Agriculture.¹³ Chronic skin ulcers were treated with live steam, cod liver oil ointment, as described by Loehr,¹⁴ or with injections of allergic serums according to the Walzer¹⁵ technic.

TOXOID THERAPY

Toxoid Used.—We used throughout this investigation a commercial stock of polyvalent staphylococcus toxoid-Lederle, which was supplied through the courtesy of the manufacturer. The producer described this preparation in a folder accompanying each vial as follows: "Detoxification of the toxin is effected with formaldehyde. It is carried to the point where the intracutaneous injection of 0.1 cc. into the skin of a susceptible rabbit will no longer cause necrosis." It should be noted that the manufacturer makes the claim that its product is valuable in stimulating antitoxin production. The preparation consisted of two dilutions: dilution 1 contained 100 "units" per cubic centimeter and dilution 2 contained 1,000 "units" per cubic centimeter. The manufacturer described the "unit" of staphylococcus toxoid as "the toxoid obtained from a

dermonecrotizing unit of toxin (the least amount of toxin which on intradermal injection in a susceptible rabbit will produce an erythema with a central necrosis at least 5 × 5 mm. in diameter").

Dosage.—The dosage of the toxoid administered was the following: The first dose of 0.2 cc. of dilution 1 was increased by 0.2 cc. with each subsequent injection until 1 cc. of dilution 1 was reached. The next dose was 0.2 cc. of dilution 2 and increased by 0.2 cc. with each dose until the final dose of 1 cc. of dilution 2 was reached. The dose was then kept at that level for subsequent injections. All injections were made subcutaneously. At times when a patient presented a severe local reaction the same dose or a slightly smaller dose was administered on the subsequent occasion. The maximum dose was never over 1 cc. of dilution 2, and no modifications were made because of the patient's age. The time interval between injections varied from two to ten days and averaged about three days. An average of 17.9 injections was given per patient over an average of forty-five days. The minimum number of doses was five, while the maximum was thirty. The minimum duration of toxoid therapy in any case was twenty-two days, while the maximum was 130 days. The average total number of "units" administered was

SEROLOGIC CONTROL

The course of immunization of each patient was followed in the laboratory by the determination at varying intervals of the antihemolysin (antitoxin?) titers of the patient's serum. An initial antihemolysin titration was done in each case prior to the beginning of toxoid therapy, and from two to nine titrations were done during and after the course of treatment. The average number of titrations for each patient was five.

Titration.—The antihemolysin titrations were originally done by determining that dilution of serum which just inhibited hemolysis of a twice washed 1 per cent suspension of rabbit erythrocytes by one minimum hemolytic dose of staphylococcus toxin, after incubation for one hour at 37 C. Subsequently a sample of the international standard staphylococcus antitoxin was obtained through the courtesy of Dr. Hartley of the National Institute for Medical Research, London,¹⁶ and after suitable preliminary tests our serums were titrated in terms of that standard. Some of the serums were titrated directly against the standard while the titers of others were transposed to international units from the titers obtained by the original method. The titers recorded in this paper are in terms of the international unit.

The technical details of the titrations and of the preparation and standardization of toxin used in titrating in the terms of the international standard antitoxin have been presented in detail in a separate communication by Blair and Hallman.¹⁷

SEROLOGIC RESULTS

Titer Prior to the Administration of Toxoid.—Blair and Hallman¹⁸ of the laboratory of the Hospital for Joint Diseases have already demonstrated in a series of eighty patients suffering from chronic osteomyelitis that the titers of serums of persons suffering from this disease generally fell prior to the administration of toxoid therapy within the range established as normal; namely, one international unit or less. Only one fifth of the serums of these individuals had an initial titer of three or more units, which is definitely above normal. The results obtained in the present series of cases of osteomyelitis are similar to those already reported by Blair and Hallman.¹⁸ This is in direct contrast to those of Dolman,¹⁹ Murray²⁰ and Gross¹⁹ in a comparable group of cases. These authors found that the titers in this type of case were markedly above normal.

Titer After Administration of Toxoid.—We found a definite rise in titer in all of the thirty-eight cases following the administration of staphylococcus toxoid. This confirms the observations of Dolman and Murray in cases of osteomyelitis and of others in superficial staphylococcal infections. These workers have found that the titer increased usually from five to ten fold subsequent to the administration of from four to eight injections of toxoid.²⁰ In our series of thirty-eight

cases the antihemolysin titers of thirty-one were increased from two to ten fold while the titers of nineteen were increased from five to ten fold, and the titers of the serums of the remaining seven patients were increased from twelve to thirty-four times. In every instance, however, the number of injections necessary to raise the titer of serums to their maximum was greater than has been reported by others. The maximum titer obtained in the serums of two patients was 28.8 international units. This represented an increase of 4.5 and 7 times the initial titers. The next highest titer was 17.7 units.

It had been previously observed that the titers obtained following toxoid therapy do not remain at the maximum level but drop to a level which is usually higher than the initial titer.²⁰

We found a similar drop in titers. This occurred during the course of injections in nine patients and after the cessation of toxoid therapy in the remaining twenty-nine cases. The titers of four patients dropped to a level lower than the initial titers; the titers of two dropped to a level equal to the initial titers, and the titers of the remaining thirty-two dropped to a level higher than the original titers. The level finally reached in the majority of instances was from two to eight times higher than the initial titer. We found no relationship between the maximum titers obtained and the final levels to which they fell. Neither was there any relationship between the extent of the rise of titers and the final levels. We have found that in general the higher titers fell somewhat more precipitately than the lower titers.

Summary.—From the foregoing observations it may be concluded that:

1. The initial titer in the majority of our cases of chronic osteomyelitis was within the normal range of 1 international unit or less.

2. Subsequent to the administration of toxoid, the titers increased from five to ten fold or more in twenty-six cases and from two to ten fold in thirty-one of thirty-eight cases.

3. These results are similar to those reported in various types of staphylococcal infections, including osteomyelitis.

4. The number of injections of toxoid necessary to raise the titers to the maximum ranged from five to thirty and averaged 17.9. This is in contrast to other reported observations in which from four to eight injections brought the titers to a maximum level.

5. The titers in nearly all cases fell from the maximum level, which was above the initial titer.

6. The higher titers appeared to fall somewhat more precipitately than did the lower titers.

Comment.—Murray²⁰ suggests on the basis of the high initial titer he found in seven cases of osteomyelitis in which the average was 11.7 units in contrast to the average of 0.96 unit in 108 cases of other than osteomyelitic staphylococcal infections that this titration might prove of diagnostic value in cases of osteomyelitis in which there is doubt as to the causative agents. Our experiences are not in agreement with this conclusion, for, as has already been pointed out by Blair and Hallman,¹⁸ in only 20 per cent of eighty osteomyelitic serums was the titer above the normal. Furthermore, a similar ratio of high titers was found in staphylococcal infections other than osteomyelitis. On the basis of these data the accuracy of this diagnostic procedure would be rather inadequate.

CLINICAL RESULTS

We find ourselves in agreement with Dolman that the evaluation of the effect of toxoid therapy or for that matter any therapy of chronic osteomyelitis is beset with many pitfalls because of the inherent characteristics of the disease.

Systemic and Local Reactions to Injections of Toxoid.—The first prerequisite of a therapeutic measure is that it should produce no harmful effects as a result of its application. In eleven of our thirty-eight patients and in two normal individuals who have submitted themselves to toxoid injections there were definite local and systemic reactions. The local reaction consisted of pain, tenderness and at times rather extensive areas of induration and redness, one of which necessitated local therapy in the form of wet dressings. One patient, following an injection, had a rise in temperature for several days. This patient had no active lesions at that time. One patient complained of "chilly" sensations on evenings following injections. A very fair number of these individuals complained of malaise, lethargy, fatigue, sensations of not feeling well and loss of appetite and, on several occasions, loss of weight. Those who complained of systemic symptoms did not look well, and a few of them had rings under the eyes. In several instances we felt obliged to discontinue toxoid therapy because of these symptoms. All these patients invariably reported sensations of well being and in a few instances of gain in weight after the cessation of the injections. The two normal individuals who submitted themselves to injections of toxoid experienced mild to severe local reactions, which were sometimes accompanied by fatigue.

A review of several reports of other investigators confirms our observations. Murray⁸⁷ stated that out of 116 adequately treated cases ten presented local reactions, seven general reactions, twelve lethargy, and sixteen exacerbations. The significance or the character of the latter group was not amplified. Dolman reported that his group of normal laboratory workers presented reactions after toxoid injections varying "from the slightest local tenderness to a painful, red, swollen arm, with mild general malaise on the day following the injection." These reactions were, however, not sufficient to preclude the advisability of continuing with the toxoid. Dolman⁸⁸ further reported that "many" patients had slight local reactions; in others it was more marked and sometimes lasted for three days. In 10 per cent there was mild headache, dizziness or nausea and fatigue. Very occasionally there was more marked swelling, slight fever and illness for a day or two. There have, however, been no serious reactions to toxoid reported.

In view of these observations, injections of toxoid are not altogether without ill effects, and occasionally the results may be somewhat disturbing. It should be recalled, however, that the administration of other biologic preparations is often accompanied by a reaction of much the same order as is encountered following the injection of staphylococcus toxoid. Nevertheless, if toxoid therapy is proved of definite value such untoward results would have to be tolerated.

Efficacy of Toxoid.—Further consideration of our data reveals that in eighteen of our thirty-eight cases new lesions developed during or soon after the course of toxoid injections. Two of these cases necessitated resaucerization of their affected bones. In one of these this procedure had to be applied when the patient's

antihemolysin titer was near its maximum level of 28.8 international units. Another patient, with a persistent sinus which could not be opened wide because of anatomic considerations, developed an extensive and long lasting pyoderma and several extensive phagedenic ulcers on the affected as well as on the opposite limb, notwithstanding that he received 24,300 "units" of toxoid and that his antihemolysin titer had increased sixfold. In another case presenting multiple soft tissue and bone abscesses involving practically every part of the body, many new foci have developed up to the present time, notwithstanding the administration of 21,300 "units" of toxoid and a fivefold increase in the antihemolysin titer. In an additional instance toxoid did not prevent a mid thigh amputation for a post-operative staphylococcal infection of a knee following an arthrodesis for tuberculosis even though the antihemolysin titer had risen to four times the original titer. Subsequently the titer rose sixteenfold but the healing of the stump was delayed over a period of three months because of a persistently stubborn infection of the operative wound. The new lesions in most of the other cases consisted of local abscesses, several of which occurred in instances in which there was no evident active lesion at the time of onset of toxoid therapy. Erosions of epithelium in healed cases of osteomyelitis were to all appearances not influenced by the action of toxoid.

I operated on a series of about 150 patients, who were submitted to maggot therapy. The only two post-operative mortalities sustained in this series occurred in individuals who were under toxoid therapy. I do not by any means attribute these deaths to the toxoid; nevertheless, I feel obliged to mention these instances to indicate the inadequacy of the toxoid to modify the course of these patients for the better. The following report is of special interest, for it presents an ideal instance for the testing of the efficacy of toxoid therapy:

CASE 1.—A white boy, aged 7 years, was admitted to the service of Dr. Samuel Kleinberg, Oct. 29, 1930, with an acute hematogenous osteomyelitis of the lower end of the tibia of several days' duration. The part was immediately incised and drilled, draining a small quantity of pus. The Orr therapy was instituted. The patient recovered from the acute phase and went on to the subacute phase of the disease. Dec. 3, 1934, the antihemolysin titer was 4.4 international units. Toxoid was then administered. After four injections the titer rose to 8.8 units. After nine additional injections, bringing the total dosage up to 5,390 "units" of toxoid, the titer rose to 15.5 international units. The last injection was administered Feb. 11, 1935; the total dosage of toxoid was 9,390 "units." On the 13th of the same month the antihemolysin titer fell to 14.4 international units and March 27 it had dropped to 8.8 international units. Notwithstanding the very satisfactory serologic response to toxoid therapy, the local lesion developed during the course of toxoid therapy into a very extensive and progressive involvement of the lower half of the tibia.

Further studies of our data reveal that the original titer had no relationship whatever with the severity or mildness of the local lesion. In addition, the serologic response was not in any way related to the clinical progress of the case. This is true of practically all our cases.

A study of the only other extensive report of toxoid in the treatment of a comparable number of cases of subacute and chronic osteomyelitis, namely that of Dolman,⁸⁸ gives little comfort, for it is a statement of generalities without detailed information to make a clear evaluation possible. Dolman's general impression

is that of beneficial results, yet there is no clinical evidence presented on which he bases that impression. He states: "In a few children with several years' history of chronic osteomyelitis, one or more discharging sinuses healed over for the first time during or soon after the administration of a course of eight injections, and there have since been no recurrences. In other instances, sinuses healed following toxoid treatment but broke down again after a few weeks." These experiences are common occurrences in the hands of all surgeons and hardly form a basis for any special claim for any mode of therapy. Dolman further states: "In a few adults with chronic osteomyelitis of long standing very striking local improvement occurred; other similar cases showed little change." This also appears to me as insufficient for any claim for efficacy in the management of chronic osteomyelitis.

COMMENT

Emphasis should be placed on the lack of correlation between the serologic and the clinical results in this series of cases of chronic osteomyelitis. A high original titer did not indicate a regressing lesion, nor did a low titer indicate a progressing lesion. Furthermore a rise, no matter how great, in titer following toxoid therapy did not signify a healing lesion. Similarly, Dolman's observations of instances which apparently improved while others showed no improvement or, if they showed a primary improvement regressed while under observation, point to the same lack of relationship between the serologic and the clinical results. It therefore would seem rational to conclude from the foregoing that the rise in titer is not the deciding factor in the course of the disease and that the development of immunity against the various toxins encompassed in the toxoid has no effect on the local lesions. Furthermore, the rise in titer seems to indicate merely an inherent ability on the part of the patients to respond to the antigenic stimuli of the toxoid.

Recent studies on the pathogenesis of staphylococci have shown that the action of the invading micro-organism is due to at least two outstanding characteristics: first, the ability to invade the host to produce purulent lesions and, second, to produce toxins. Thus one finds that Burky²¹ has separated pathogenic staphylococci into two groups on the basis of this conception. One group, which he isolated from chronic indurated lesions of the skin and mucous membranes, was highly toxigenic with but little invasive capacity, while another group, which he isolated from "purulent lesions such as styes, osteomyelitis and lung abscesses," was markedly pyogenic with but little toxic producing capacity. Similarly, Gross²² obtained his least toxic staphylococci in cultures from osteomyelitis. Our own studies confirm these results for our observations show that the majority of the strains from chronic osteomyelitis are not highly toxigenic.

A clinical consideration of the great majority of cases of chronic osteomyelitis reveals that the outstanding feature is not the toxemia but the purulent character of the lesion. On the other hand, in instances of acute osteomyelitis in which toxemia plays an important rôle, it may be possible to control the toxemia passively by the administration of antitoxin or actively by immunization with toxoid. This, however, has little effect on the invasiveness of the organism, and pyemia may not

be checked. Thus Parish²³ expresses the opinion that antitoxin "is likely to be the most effective in cases in which toxemia is predominant. . . . It is a rational form of therapy, for theoretically, at least, a serum which neutralizes toxins impedes one of the most important modes of attack by the staphylococcus and thereby aids the natural defenses of the tissues. On the other hand, one has to admit that contradictory reports have been made as to its usefulness. Its effects on the invasive properties of the coccus has not yet been determined, and it cannot be expected to take the place of surgery in such conditions as osteomyelitis, and staphylococcal abscess of the kidney, although it may be a useful adjunct." Burky²¹ has made a similar suggestion; namely, "the fact that an antitoxin can be produced suggests its use in cases of staphylococcus infections. However, the value of such therapy in (Burky's) group II (osteomyelitic) infections awaits proof. . . . it is possible that the pathogenicity of these strains lies in some factor that antitoxin could not neutralize."

This is further borne out by the fact that in infections in which the toxigenicity of the infecting organism plays an important rôle, namely, superficial infections, toxoid therapy has been reported to be of definite benefit. In deep-seated infections, on the other hand, the stimulation of antitoxin (antihemolysin) production, by immunization with toxoid, has produced no beneficial effect on the course of the disease. In fact, some patients developed new lesions during the period of toxoid therapy. It should also be noted in this connection that an individual subject to recurrent furunculosis does not as a rule develop osteomyelitis. The reverse is also true.

It would therefore appear, from the foregoing considerations, that, if an attempt is to be made to induce immunity in patients with chronic osteomyelitis, the effort should be directed toward the establishment of resistance to the invasiveness of the organism rather than to the production of a purely antitoxic immunity.

SUMMARY

1. An attempt was made to immunize a series of thirty-eight patients suffering from chronic osteomyelitis by the administration of staphylococcus toxoid.
2. The progress of immunization was followed by the determination of staphylococcus antihemolysin (antitoxin) in the serums of patients.
3. Subsequent to the administration of staphylococcus toxoid the antihemolysin titers increased in all cases from two to thirty-four times the original titers.
4. The magnitude of the titer gave no indication of the clinical status of the case.
5. A rise in titer did not indicate a regression of the lesion.
6. A rise in titer did not prevent a development of new lesions in eighteen out of thirty-eight cases.
7. A rise in titer did not expedite the healing of existing lesions.
8. A rise in titer did not prevent the progression of old lesions. (Two cases necessitated resaunderization, one case came to amputation, and two ended fatally—the only instances in a series of more than 150 cases).
9. In a discussion of our observations it is suggested that the disappointing results obtained following the administration of staphylococcus toxoid in chronic osteomyelitis may be attributed to the fact that staphy-

lococci causing this type of infection are of low toxigenicity and of high invasiveness. I believe that immunization in this type of infection should be directed toward the establishment of resistance to the invasiveness of the organism rather than to the production of a purely antitoxic immunity.

SYPHILITIC AND NONSYPHILITIC PERSONS ON THE FULTON COUNTY, GEORGIA, RELIEF ROLLS

A COMPARATIVE STUDY

J. G. McDANIEL, M.D.

ATLANTA, GA.

This study was made to determine the prevalence of syphilis among the unemployed in Fulton County, Georgia, on the FERA rolls, and to compare the chief complaints and physical condition of those men found to have syphilis with a given number of those not having syphilis and to determine whether syphilis has any effect on the physical capabilities of a man to earn a livelihood. The presence of the disease was determined by the blood Wassermann test.

It was the rule in Fulton County to subject every applicant applying for federal relief to a physical examination and give a medical work classification before assigning the applicant to any work project. We used a simple uniform medical terminology, exam-

five medical work classifications, depending on the man's physical ability to work. The classifications are as follows:

- Good physical condition; capable of doing hard work.
- Some defect found, such as hernia, hemorrhoids, slight heart trouble, mild hypertension, or debility because of age. Capable of doing light work or indoor work, not requiring much physical strength.
- Some rather marked defect found, as heart trouble, hypertension, marked debility from age, or deformity. Very, very light work.
- Not able to do any kind of work. (There is but little difference between C and D.)

LA, or Leave of Absence. Reserved for those with acute infections, injuries or some malady amenable to treatment in a relatively short period of time, such as colds, tonsillitis, venereal diseases or accidents. A leave of absence could be given a man for as long a time as the physician felt it should normally take him to recover; he would then report back for examination and classification. All men with a urethral discharge and sores on the genitalia were given leave of absence until well.

If the physician assigned a man to a work classification other than A, he stated his reason for so doing under the title of chief pathologic condition on the chart. For example, if a man had a bad heart and the examining physician felt that he was not able to work, he gave him the medical work classification of D and under chief pathologic condition listed "heart."

This study was made by going over the examinations of 545 men, white and colored, who had positive Wassermann reactions and tabulating the number of times each chief complaint occurred, each physical abnormal-

ity, the chief pathologic condition, the blood pressure and the medical work classification, then comparing them to the same tabulation of 1,000 men, white and colored, whose Wassermann reactions were negative. These thousand examinations were selected at random. Men were used because they lent themselves more readily for a complete examination and could be given more definite medical work classifications.

It is noteworthy that 67 per cent of those having syphilis (chart 1) were between 20 and 39 years of age and only 3 per cent were beyond 60, whereas 54

per cent of the nonsyphilitic were between 20 and 39 years and 5 per cent beyond 60 years.

Strangely enough the four major complaints, namely, dizziness, nervousness, headache and heart trouble, were complained of more frequently in the nonsyphilitic (chart 2), nearly all the other complaints being more frequent in the syphilitic. When the actual physical abnormalities were tabulated, however (chart 3), a greater percentage was found in the syphilitic in all except hydrocele and amputations. Two and one-half times as many perfectly normal men were found among those not having syphilis. It must be remembered that many of these physical abnormalities may in no way interfere with a man's ability to work; for instance, an applicant might have some decayed teeth, impaired vision and small varicose veins and still be able to do good work. Under the chief pathologic condition, however, are listed abnormalities of sufficient magnitude either to hinder or to keep a man from working (chart 4); here, as in the physical conditions, one finds much more that is pathologic in persons with syphilis.

Study of the comparative blood pressures from 16 to 19 years and then for each ten year period there-

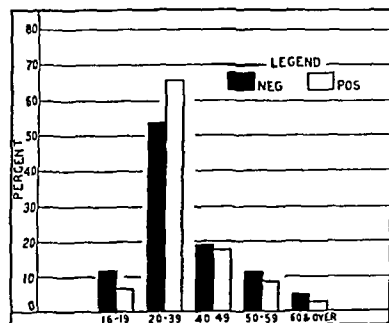

Chart 1.—Comparison by age.

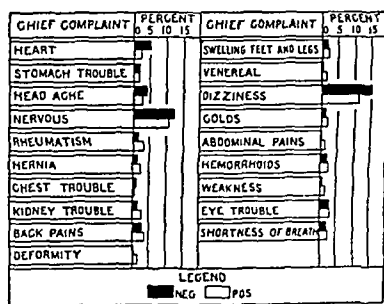

Chart 2.—Comparison by chief complaint.

ining from May 15, 1935, to Nov. 15, 1935, 6,911 applicants for relief rolls, of which number 1,311 had syphilis, an average of 18.9 per cent. In the Negro, 33.8 per cent of the men and 34.5 per cent of the women had positive Wassermann reactions; 7.1 per cent of the white men and 7.3 per cent of the white women had positive Wassermann reactions.

Short medical histories, weights, heights and eye examinations with the Snellen chart were recorded by the nurses on the applicant's chart before he went into the examining room; there he was allowed to undress completely in a booth and come to the examining room when his name was called. Here he was asked if he was in good health or if anything hurt or bothered him. Any complaint made was listed under the title of chief complaint. We then proceeded to give him a thorough physical examination, recording all physical abnormalities. Following this blood for a Wassermann test was taken and the physician immediately gave him one of

This study was made possible through the FERA. Particular credit is given to Mr. W. W. Daniel and his co-workers for their invaluable assistance in the compilation of the statistics and to Mr. Allen Lillywhite, formerly connected with the local administrator, for his timely suggestions; also the administrators of county and state, who cooperated.

after did not reveal anything unusual in the different age groups past 20 years not shown in the composite chart (chart 5). The small 16-19 year age group is interesting because of the low and high pressures in those who are syphilitic and should have more study (chart 6).

Most important of the entire study is the comparative medical work classifications. In the 16-19 year age group (chart 7) one finds a few more of the boys

The 40-49 age group (chart 9) shows a shifting of those having syphilis to light work and leave of absence. The men from 50 to 59 (chart 10) normally carry hard and light work because of their advancing years. It is obvious that a great many men in their late fifties physically sound could not do hard work; hence we find fewer of the syphilitic in these two classifications and more of them in the C, D and LA classes, able to do little or no work.

able to do hard work in the nonsyphilitic column. Those youngsters in the C and D classifications were so assigned chiefly because of extreme youth or congenital abnormalities. The next age group, 20-39 years (chart 8), includes the largest number of men, the age that man should reach the height of physical endeavor. Here one notes seventy-eight per hundred of the nonsyphilitic able to do hard work, whereas only sixty-one per hundred of the syphilitic could do hard work, a difference of seventeen men. These men are not totally and permanently disabled because we find them in B, C and LA, either doing light work or recovering from some acute malady.

COMMENT

Clinically, this study proves conclusively that syphilis may attach itself to any structure of the body. As to whether it attacks that part which has been made vulnerable by some other malady and on which it heaps its insult, or whether it alone is responsible for the increased amount of pathologic change found in the syphilitic, I am unable to say. Certainly there were some individuals who were hale and hearty in spite of syphilis and advancing years. Be that as it may, if about 34 per cent of our Negroes and 7 per cent of our white persons have syphilis and of that number 17 per cent between 20 and 40 years

are not able to do competitive work, and 16 per cent of those past 50 years are not able to work at all, then syphilis is a serious disease from an economic standpoint. Certainly to be considered too is the comparatively rapid drop in the number of the syphilitic from 39 years to 60 years and over (chart 1). This rapid decrease can only mean that a large number having had syphilis have either died, been treated or are not able to report for examination.

No doubt one could select any disease and find a goodly number of persons not only suffering from it but disabled. There is no disease that I know of, however, found in such large numbers, that responds so beautifully to treatment as does syphilis, nor can I think of one that has a longer latent period before serious symptoms manifest themselves, thereby affording a golden opportunity for diagnosis and cure or at least an arrest of the disease.

CONCLUSIONS

1. No orderly train of symptoms could be found resulting from syphilis.

2. Clinically all physical abnormalities were more frequent in persons who had syphilis.

3. In the very young the blood pressure may be markedly affected, either low or high, and should have more study.

4. Syphilis very definitely handicaps a man in his struggle to earn a livelihood.

5. Syphilis is a serious problem, to us not only as physicians but as citizens of Fulton County, Georgia, and the nation.

Grand Theatre Building.

THE MEDICAL TREATMENT OF MÉNIÈRE'S SYNDROME

MADELAINE R. BROWN, M.D.

Assistant in Neurology, Massachusetts General Hospital; Research
Assistant in Neurology, Boston City Hospital; Assistant in
Neurology, Tufts Medical School

BOSTON

In January 1861 at the Imperial Academy of Medicine of France, Prosper Ménière delivered a paper entitled "Memoir Concerning Lesions of the Internal Ear Giving Rise to the Symptoms of Cerebral Apoplecticiform Congestion." This paper was important for two reasons: it was the first time that the syndrome of deafness and tinnitus accompanied by attacks of vertigo, vomiting and nystagmus had been related to the inner ear, and, secondly, it contained the description of an autopsy as a result of which generations of medical students have been taught that these attacks were due to hemorrhage into the labyrinth. Today it is realized that the pathologic anatomy is unknown. It has been impossible to localize the lesion in any one part of the auditory tract. Therefore many forms of therapy have been tried: lumbar puncture, quinine, mastoidectomy, labyrinthectomy and, finally, section of the vestibular portion of the eighth nerve. Of these the last named has been the most successful.

It was called to Furstenberg's¹ attention that dizziness was a common symptom of patients suffering from

Read before the Boston Society of Neurology and Psychiatry Nov. 19, 1936.

From the Department of Neurology, Massachusetts General Hospital, and the Neurological Unit, Boston City Hospital.

The author was assisted by Miss Dorothy Hale and Miss Elizabeth Fritz, of the Social Service Departments of the Boston City and Massachusetts General hospitals, in following up patients.

1. Furstenberg, A. C.; Lashmet, F. H., and Lathrop, F.: Ménière's Symptom Complex: Medical Treatment, *Ann. Oto., Rhin. & Laryng.* 43: 1035 (Dec.) 1934.

cardiovascular renal disease and that in them the water balance might be at fault. On examination of the literature he found Danish articles² describing the successful treatment of Ménière's syndrome by dehydration and a low salt diet in 150 of a series of 157 patients. With Lashmet's and Lathrop's assistance he undertook some exceedingly careful experiments to determine whether the electrolytes or the water in which they were excreted was the important factor. They concluded that sodium was the factor and that the addition of ammonium chloride to the diet prevented the storage of sodium. Fourteen patients were treated by the Ann Arbor workers. In their series sodium always precipitated an attack, while the elimination of sodium from the body gave complete relief.

Six patients from the neurologic outpatient department of the Boston City Hospital and six from that of the Massachusetts General Hospital have been placed on a low sodium diet with the addition of ammonium chloride. On this regimen, over periods ranging from six months to twenty-two months none of these patients have suffered a severe attack, although mild dizziness and a feeling of fullness in the head may remain. In four a lapse in therapy was followed by an attack. Two patients have been free from attacks, although therapy was discontinued after three months and one year respectively.

Although one sufferer from dizziness due to hypertension was relieved by a low sodium diet, four patients complaining of vertigo unaccompanied by deafness were not relieved by the diet and ammonium chloride.

It must be stressed that Ménière's is a definite syndrome. Many of the unsuccessful attempts at medical treatment have been due to faulty diagnosis. The symptoms of deafness and tinnitus, at least before an attack, are the two that are most commonly overlooked. These are just as much a part of the syndrome as vertigo and vomiting and must be present before the diagnosis can be established. The Bárány test is not of great assistance in diagnosis. Although some had hypoactive or hyperactive labyrinths, many of these patients gave normal reactions. In one patient the labyrinth was dead. In five patients, deafness of a mixed type was attributed to a previous otitis media; in one patient, to an otosclerosis; in five patients, nerve deafness alone was present; in one patient, deafness was present only before an attack.

According to expectations, many practical difficulties arose in keeping clinic patients—many of them foreigners with considerable language difficulty—on a strict diet. All of Furstenberg's fourteen patients were hospitalized for thirty days or more, while all the patients in this series were treated in the outpatient department. Sometimes two or more visits were necessary before a low sodium regimen was attained, but one great advantage in treating these patients is that a sufferer from true Ménière's syndrome is eager and ready to do anything in his power to avert attacks.

An unexpected source of sodium appeared in the course of this study. Since these patients had nausea or vomiting, it was quite natural that they should use sodium bicarbonate or compound effervescent powders. The apparently unsuccessful treatment of two patients was remedied by eliminating these medications.

REPORT OF CASES

CASE 1.—A man, aged 54, seen Feb. 12, 1935, stated that yearly attacks of tinnitus, vertigo, vomiting and diplopia had begun five years before. A week before admission he had four in one week. There was mixed deafness and a dead labyrinth on the right. He was put on a diet plus 10 grains (0.6 Gm.) of ammonium chloride three times a day. August 14 he felt well and had no severe attacks. When the patient was seen Feb. 7, 1936, he had had two mild attacks, and the dose of ammonium chloride was raised. June 3 there had been no severe attack. December 15, one attack after exertion. He had not been taking a full amount of ammonium chloride or adhering strictly to diet.

CASE 2.—A woman, aged 51, seen March 22, 1935, stated that attacks of vertigo, vomiting and loss of consciousness had begun one year before. Tinnitus and bilateral mixed deafness were found. She was placed on the regimen. No attacks occurred until July 1935, when three weeks after discontinuing the diet and medication she had a severe attack. She returned to her diet and had had no attacks and was feeling very well March 1,

*Furstenberg's Treatment and Diet**

1. Low salt content.
2. Medication. Ammonium chloride 3 Gm. with each meal, in capsules (six capsules each containing $7\frac{1}{2}$ grains [0.5 Gm.] taken during the meal), three days on and two days off. The capsules should not be replaced by the chocolate coated or the enteric coated pills because the latter sometimes pass through the gastro-intestinal tract without being absorbed. The ammonium chloride can be given in this dosage for an indefinite time without injurious effects. We have had patients with nephritis receiving ammonium chloride in this manner for a period of five years.
3. Water intake unrestricted.
4. Diet, approximate neutral, low sodium diet.
 - Group A: The following foods may be taken daily:
 1. Eggs, meat, fish and fowl as desired.
 2. Bread as desired.
 3. Cereal, one of the following: farina, oatmeal, rice, puffed rice or puffed wheat.
 4. Potato and one or more servings of any of the following: (a) macaroni, (b) spaghetti, (c) rice, (d) corn, (e) cranberries, (f) prunes, (g) plums.
 5. Milk as desired.
 6. Vegetables and fruits daily of any fruit and of any vegetable not included in groups B and C as desired.
 7. Butter, cream, honey, jellies, jams, sugar and candy permitted as desired.
 8. Tea and coffee as desired.
 - Group B. Foods to be avoided: All salt meats and fish, or bread, crackers and butter prepared with salt. Carrots, clams, condensed milk, raisins, caviar, cowpeas, olives, spinach, cheese, endive, oysters.
 - Group C. Foods to be taken no more than twice weekly: Lima beans, beets, buttermilk, cantaloupe, cauliflower, celery, chard, dried coconut, dried currants, dates, figs, horseradish, kohlrabi, limes, muskmelon, peanuts, peaches, mustard, pumpkin, radishes, rutabagas, strawberries, turnips, turnip tops, watercress.

* Contains about 87 milliequivalents of sodium.

Note: All food to be prepared and served without salt.

Preparations containing sodium to be avoided: Sodium salicylate, bicarbonate, bromide, tartrate, iodide, nitrite, phosphate, thiosulfate, benzoate, sodium phenobarbital and amyral, compound effervescent powders, potassium and sodium tartrate and baking powder.

1936. When seen July 26 there had been no attacks. She discontinued the diet in March and when seen November 12 there had been no attacks.

CASE 3.—A man, aged 62, seen May 12, 1935, had had attacks of vertigo once a month for one year, vomiting and loss of consciousness. The left ear felt closed. He had arteriosclerosis and hypertension. He was given the full regimen. June 25 he vomited ammonium chloride so he stopped it. August 6 he was losing weight on a salt-free diet. There had been no attacks. He was taken off the diet. October 1 he had gained weight and felt well. Jan. 4, 1936, he reported that he had had an attack October 21. May 25 he reported that he had had many attacks. He is now trying a low sodium diet again but Jan. 18, 1937, reported many attacks.

CASE 4.—A man, aged 59, admitted May 15, 1935, had had attacks of tinnitus, vertigo and unconsciousness for three years. There was old chronic catarrhal otitis media, bilateral mixed deafness and past pointing to the right. The regimen was started. June 5 the condition was improved. There had been no attacks. October 4 there had been no attacks. The patient had ceased to take ammonium chloride but was on a fairly salt-free diet. March 25, 1936, he complained that his legs were giving out from under him. There was no mention of

attacks. May 27 he stated that he had two types of attacks now once or twice a month, vertigo and sudden weakness in the legs. He had been eating salt and had taken compound effervescent powders for years. He was given the low sodium diet again. December 4 he reported that no attacks had occurred. Deafness has increased.

CASE 5.—A man, aged 64, seen May 20, 1935, complained of attacks of vertigo. In September 1933 mastoidectomy was done on the right and section of the right eighth nerve was done one week later. There had been no change in attacks since. He was placed on a salt-free diet and ammonium chloride 15 grains (1 Gm.) three times a day. July 15, 1935, the condition was better. There had been no attacks. May 13, 1936, there had been no attacks since he was placed on the diet. He took ammonium chloride for only from four to six weeks. He complained of deafness in the right ear and tinnitus. He ate bread and butter containing salt, but otherwise he did not use it. He was given a diet sheet. November 15 he felt a little unsteady.

CASE 6.—A man, aged 38, seen Aug. 13, 1935, had his first attack in June; five had occurred since that time. He complained of vertigo, vomiting, mixed deafness and perforated drum of the left ear. The Bárány test was negative. He had lost 40 pounds (18 Kg.) and was placed on the regimen. October 21 he reported no attacks. The condition was much improved. He was gaining weight. July 14, 1936, he had had no attacks. He went off the regimen in November 1935.

CASE 7.—A woman, aged 37, seen Oct. 24, 1935, complained of attacks of vomiting and vertigo. She was placed on a diet plus 4 Gm. of ammonium chloride a day, by the Waltham Hospital, to which she had been admitted in May 1935. She had no attacks until September, when she had omitted ammonium chloride for a month. There was nerve deafness of the right ear and a hypo-active labyrinth. She was given 3 Gm. of ammonium chloride three times a day after meals, three days on, two days off. Jan. 14, 1936, she reported that there had been no attacks. She felt better than she had for years. April 15 she felt very well and reported no attacks. November 10 she had had no attacks.

CASE 8.—A man, aged 48, seen Nov. 8, 1935, had had one or two attacks of vertigo and falling daily and then none for several days since March. There was running of the ear one year before, mixed deafness, more in the left ear, tinnitus and staggering. He had arteriosclerosis. The blood pressure was 180 systolic, 110 diastolic. There was mild Parkinson's syndrome. He was given the regimen. December 12 he felt much stronger and was walking well. There had been no severe attacks, only one or two minor ones. May 6, 1936, he reported one moderately severe attack in February while shoveling snow. He had been eating WPA meat containing sodium. He had headaches. August 12 he had had no attacks and had gained 8 pounds (3.6 Kg.) since November 1935. December 18 he was feeling very well. No attacks had occurred.

CASE 9.—A woman, aged 45, seen Nov. 27, 1935, had had tinnitus, vomiting and vertigo which lasted one day, two years before. The preceding June she had another attack and had not felt herself since that time. She had five more attacks at intervals of two weeks. She had been treated for chronic catarrhal otitis media for many years and bilateral mixed deafness. She was placed on 1.5 Gm. of ammonium chloride three times a day after meals, three days on and two days off, and a low sodium diet. April 1, 1936, she reported no attacks. She felt well. Tinnitus was improved slightly. May 13 she felt very well and had had no attacks. When she was seen in September and again in January 1937 no attacks had occurred.

CASE 10.—A man, aged 42, seen Dec. 3, 1935, had had onset of attacks of tinnitus, vertigo and nausea six years before. Now he was having them once a week. His father was deaf and had similar attacks. There was mixed deafness, more on the right. He was unable to work or drive a car. He was placed on a full dose of ammonium chloride and a salt free diet. December 17 he stated that he had one attack the day after he started the diet. He was driving a car and feeling well. There was a little transitory dizziness. Jan. 14, 1936, he reported that he had had two attacks, one the day after eating a Christmas dinner containing salt and one after a dose of sodium bicarbonate. At the time of examination he was feeling well. April 1 he had one mild attack. He was feeling well and was driving a postoffice truck. July 7 he reported that he had discon-

tinued his diet for two weeks and had a very severe attack June 14, in which he lost consciousness, and has not felt well since. He is back on the diet. In August he felt well. There had been no attacks. In January 1937 he was feeling well. He had had two brief attacks in spite of a full regimen. He had been taking potassium chloride also.

CASE 11.—A man, aged 59, seen Dec. 19, 1935, had had four attacks of tinnitus, vomiting and vertigo during the past year. The last one was December 4. There was nerve deafness. He was given the regimen. Jan. 23, 1936, there had been no attacks but a little dizziness at night. May 26 he had had no attacks and had lost 10 pounds (4.5 Kg.).

CASE 12.—A man, aged 49, seen May 7, 1936, complained that two years before he had had deafness and tinnitus of the right ear. Eleven days before examination there was a sudden attack of vertigo to the right with no vomiting. Tinnitus ceased two years before. Lying on the right side would bring on an attack. Nerve deafness was present. The regimen was started. May 21 there had been no severe attacks. He could now lie on the right side. There was some tinnitus of the left ear. June 30 there had been no attacks. He had lost 16 pounds (7.3 Kg.) and felt that pills were hard on the stomach. Ammonium chloride was reduced to three 5 grain (0.3 Gm.) pills with each meal. July 21 he reported one attack of vertigo, after which he returned to the full dose of ammonium chloride. August 26 he felt well. There had been no attacks.

SUMMARY

Severe attacks of vertigo and vomiting in twelve patients suffering from deafness and tinnitus have ceased under the medical treatment described.

412 Beacon Street.

PROTEIN, SALT AND FLUID CONSUMPTION OF 1,000 RESIDENTS OF NEW YORK

BENJAMIN I. ASHE, M.D.

AND

HERMAN O. MOSENTHAL, M.D.

NEW YORK

Various workers in nutrition have stated that a daily protein intake of from 75 to 100 Gm., a daily salt intake of from 2 to 4 Gm.¹ and a fluid intake of from 1,000 to 2,000 cc. are suitable or optimal components of an adequate diet. In the United States particularly it has been believed that most people eat from 75 to 100 Gm. of protein daily.² Von Voit³ suggested 118 Gm. of protein as a desirable daily intake. McLester⁴ favors 100 Gm. daily for stamina and vigor. Studies on the twenty-four hour urines which yielded information for the urea, salt and fluid excretion have been made since 1920 on normal individuals who appeared for health examination. These studies provide material for an analysis of the habitual diet of residents of New York City. The study comprises 1,000 such individuals, normal so far as they knew, who came for a "check up" because of their interest in a "health examination," or because a relative had been found to have diabetes or hypertension or for some such reason. From this study were omitted all cases that presented diarrhea, edema or any illness other than a hypertension first made known as a result of this examination. While the subject was on his usual diet there was obtained in each case (1) the volume of urine in twenty-four hours, (2) the sodium chloride excretion, (3) the urea

excretion, (4) the hemoglobin and red blood cell count, (5) the blood pressure, (6) the blood urea nitrogen, (7) the blood uric acid, (8) chemical and microscopic analysis of the urine, and in most cases (9) the blood sugar, (10) the blood cholesterol and (11) the blood chlorides.

The data are presented as follows:

1. The protein intake of group A (563 normal individuals), group B (298 individuals who, although they did not know it before this study, showed an elevation of blood pressure over 145 systolic, 90 diastolic in younger people and over 150 systolic, 96 to 100 diastolic in older people), and group C (139 individuals who showed for the first time to their knowledge not only an elevation of blood pressure but also a blood urea nitrogen of from 20 to 40 mg. per hundred cubic centimeters).

2. The salt intake of groups A, B and C.

3. The fluid intake of groups A, B and C.

METHOD

The determination of the amount of protein, salt and fluid intake was based on the nitrogen, sodium chloride and total fluid output in the twenty-four hour urine. This remains the most feasible laboratory method since in normal individuals, especially when a large series is studied, slight positive balances in some subjects are offset by negative balances in others. In previous observations it was found that the urea nitrogen as determined by the hypobromite method was really equivalent to the total urinary nitrogen.⁵ Consequently the values obtained by the hypobromite method were regarded as representing total nitrogen and will be so termed in the subsequent discussion.

The sodium chloride in the urine was estimated according to the method of Volhard.

In the calculations of the protein intake from the urinary nitrogen, allowances were made for nitrogen loss in the feces. Lusk,⁶ Mosenthal,⁷ Peters and Van Slyke⁸ and others have shown that only from 6 to 10 Gm. of protein (from 8 per cent to 10 per cent of the protein eaten) is lost in the stool. Thus the computations based on urinary nitrogen plus 10 per cent for nitrogen lost in the stool furnish a satisfactory formula for estimating protein consumption.

The calculation for protein intake is as follows: Urine urea grams (as obtained by hypobromite method) $\times 0.46$ (nitrogen comprises 46 per cent of urea) equals urine nitrogen. Urine nitrogen $\times 6.25$ equals amount of protein represented by the urinary nitrogen (nitrogen is 16 per cent of protein). These two steps may be combined by multiplying the urine urea grams by 2.87 (0.46×6.25 equals 2.87). If to the factor 2.87 is added one tenth (0.28) to represent the one tenth of protein nitrogen of the intake that is lost in the stool, the factor is approximately 3. Hence the twenty-four hour urine urea figure multiplied by 3 yields the amount of protein represented in the urine and stool. It should be borne in mind that the calculations used in this study have allowed for the protein of the stool.

With regard to estimations of the fluid intake on the basis of urinary output, Soderstrom and Du Bois⁹

cite the fact that when 1,894 cc. of water is taken the output is 1,750 cc. (a difference of 144 cc.), so that for practical purposes the urinary fluid output may be taken as approximately the fluid intake, particularly when a large series is studied in which positive balances counteract negative balances.

The specimens of urine were collected without difficulty. Ordinary traveling bags were used containing

eight wide-mouthed 20 ounce bottles in which each urine specimen was voided separately. The subjects followed their routine occupations, ate their usual meals and kept a record of their food and fluid intake during the twenty-four hour period of observation.

PROTEIN INTAKE

Table 2 shows that 9 per cent of the subjects in group A ate 20 Gm. of protein daily, or less than half the so-called 45 Gm. "minimal" protein intake; 61 per cent of these normal subjects ate 42 Gm. or less of protein daily; 89 per cent were eating 60 Gm. or less of protein daily. Only forty subjects, 7 per cent of the group, ate 75 Gm. or more of protein daily. These figures for protein consumption must appear surprising when it is shown that half the group ate less than what is felt to be an adequate minimal protein allowance, and only 7 per cent ate the 75 to 100 Gm. that has been advocated as the more fitting daily ration (tables 1 and 2).

Denis and Borgstrum,¹⁰ Brooks¹¹ and Beard,¹² working with a large number of male medical students who had an ample supply of food and could eat as they pleased, showed that the protein consumed daily was about 71 to 79 Gm. for a person weighing about 70 Kg. Lusk¹³ felt that a great number of medical students in New York City do not have an output of over 12 Gm. of nitrogen daily and believed the average protein intake of these students to be about 75 Gm. daily.

The data presented in this study coincide with those of Hetler,¹⁴ of Sherman¹⁵ and of Mendel.¹⁶ Hetler,¹⁴ in studies of the women of the Iowa State College in 1927, found that these subjects would take as high as 70 Gm. of protein daily but more often would consume only from 25 to 40 Gm. From studies of the twenty-four hour urine in 1932, Hetler concluded that the average nitrogen excretion was 7.69 Gm., representing 48 Gm. of protein. Sherman¹⁵ reported on 109 experiments indicating an average of 44 Gm. of protein and ranging from 21 to 65 Gm. Mendel¹⁶ in 1932 said:

In health, the nitrogen content of the kidney output furnishes a reliable index of the nitrogenous (or protein) intake. During the nineties of the last century the estimated protein intake, after due allowance for fecal loss of nitrogen generally approximated an average of at least 100 Gm. (16 Gm. N \times 6.25) a day. In the course of the years, these annually secured estimates are showing lower averages. Other teachers have had similar experiences. The newest figures of Hetler on young women in Illinois studied during the years 1928-1930 averaged 7.7 Gm. of nitrogen (equivalent to about 50 Gm. of protein metabolized) daily.

It has been pointed out by many workers that a low protein ration is not conducive to general health or to mental or physical efficiency. "Nutritional" edema, fatigue, anemia, cloudy swelling of vital organs, lack of resistance to infection, pellagra and other ill effects have been cited.

It is profitable to compare the extremes among this normal group A as to its use of protein. The "low protein group": (1) females constituted most of this group; (2) low or low-normal blood pressure readings are encountered frequently, yet the "high protein" eater does not have a high blood pressure; (3) underweight occurs frequently; (4) mild secondary anemia is com-

mon; (5) the blood urea nitrogen is often found to be from 8 to 10 mg. per hundred cubic centimeters as compared to from 12 to 15 mg., the standard normal.

The "high protein group": (1) males comprised most of this group; (2) the blood pressure is not elevated; (3) these individuals are of average weight, though very rarely overweight is noted; (4) no anemia is demonstrated and rarely a high red blood cell count is seen (e. g., 6,480,000); (5) the blood urea nitrogen figures in a few cases are the upper limit of normal; e. g., from 15 to 18 mg. per hundred cubic centimeters. Yet high protein feeding seems, in the cases comprising this study, to have less effect in keeping the blood urea nitrogen at the high normal figure than has a low water excretion. Thus, while the "low protein eater" tends toward a low blood pressure and a low hemoglobin percentage, the "high protein eater" has no increased blood pressure and his hemoglobin is normal.

Table 3 shows that 57 per cent of the subjects in group B (170 cases) ate 42 Gm. or less of protein daily. This is a close approximation to the 61 per cent of the normal group, who ate a similar low protein ration. Only 4 per cent of these hypertensive persons ate 75 Gm. or more of protein daily. When these 298 subjects of essential hypertension with no impairment of renal function are considered, it is found that these people, if left to their own choice, on their habitual diet since they were unaware of an existing hypertension, were eating practically the same amount of protein as nonhypertensive persons. The same was found to be true of their salt and their fluid intake.

Many of the patients found to have hypertension were seen several times in the course of the years over which this study was made, some of them having followed a low protein diet for periods of from three months to a year. There is no evidence to show that

a low protein diet will materially reduce the blood pressure. In the very few instances in which some appreciable drop in blood pressure occurred, protein and total diet restriction had been extreme and had resulted in anemia, undernutrition and general weakness. In several cases low protein intake by patients with hypertension was compensated by an excessive carbohydrate intake to satisfy hunger, which resulted in an increase of weight, thereby handicapping the patient.

Table 4 shows that even the hypertensive person with slight renal insufficiency unknown to the patient does not differ widely from the normal as to the protein content of his diet. The same is true of the salt and fluid intake.

It might be urged that nitrogen retention in these subjects may have caused a low urinary urea excretion so that the protein intake estimations for this group may be low. However, ninety-four out of this group of 139, or 67 per cent of the total, had blood urea nitrogen figures ranging from 20 to 25 mg. per hundred cubic centimeters or but slightly above the average normal; their urinary urea output and, by computation, their protein intake fell within the same range as those of the normal subjects, the hypertensive subjects with normal blood chemical changes and the hypertensive subjects with blood urea nitrogen figures of from 26 to 40 mg. per hundred cubic centimeters.

SALT INTAKE

As shown in table 6, 57 per cent of the subjects in group A ate over 8 Gm. of salt daily; eight individuals ate over 20 Gm. of salt daily, two of these taking as high as 40 Gm. a day (five of these eight subjects were overweight). The "low salt eaters" were chiefly females; the "high salt eaters" were mainly males. Among the "high salt eaters" there was a tendency toward a high

normal blood urea nitrogen (from 15 to 18 mg. per hundred cubic centimeters) and a high normal blood uric acid (from 3.5 to 4.5 mg. per hundred cubic centimeters).

Six persons of group C ate from 18 to 28 Gm. of salt daily.

FLUID INTAKE

Among the normal individuals, the "high fluid" consumers may be compared with the "low fluid" users. The "high fluid" normal: (1) males make up the major-

ity of this group; (2) the group is equally divided as to obese and thin persons; (3) the blood urea nitrogen is low normal. There is no relation between high fluid and high salt intake. The "low fluid" normal: (1) females comprise most of this group; (2) obesity is often present; (3) there is a fair incidence of the upper limit of normal blood urea nitrogen (from 15 to 18 mg. per hundred cubic centimeters) and of the upper normal limit of blood uric acid (from 3.5 to 4.5 mg.). The relatively high blood urea nitrogen and uric acid in persons who drink but little fluid is interesting in view of the fact that there has been noted a slight increase in the nitrogen elimination if copious amounts of water are taken. This is thought by Hawk¹⁷ to demonstrate the fact that water drinking actually induces increased protein metabolism and is not to be thought of as merely a "washing out" process but rather as a form of "specific dynamic action."

Fluid taken by group B (table 10) is essentially the same as by group A (table 9). It is to be noted that 1,500 cc. or more of fluid was taken by only 30 per cent of the subjects in group C (table 11), as compared to 40 per cent in groups A and B. Whether the slight nitrogen retention of this group is explainable, at least for some of its members by their low fluid intake or whether the two results are merely a coincidence is debatable. It is difficult to see why nitrogen retention of from 20 to 40 mg. per hundred cubic centimeters (in most cases from 20 to 25 mg.) would cause a low fluid output, since urea is an excellent diuretic. It must be noted, as has already been pointed out, that the normal individuals who take little fluid manifested high normal blood urea nitrogen.

SUMMARY AND CONCLUSIONS

1. It was felt from this study of 1,000 cases that the minimal requirement in a study of protein, salt and water consumption is the twenty-four hour urine sample. The patient's statement and even his record of food consumed may be very misleading. Thus we may cite a patient with Bright's disease (not included in this series) who believed himself to be on a low protein diet but who was found to be deriving more than 100 Gm. of protein daily from bread, cereals and cheese.

2. Many people eat less than 45 Gm. of protein daily. Sixty per cent of 1,000 subjects in this study were found to be eating 42 Gm. or less of protein daily (table 5). The evil effects of such a course have been pointed out.

3. The majority of the individuals studied were found to take a low protein (42 Gm. or less), moderately high salt (from 4 to 8 Gm. or more) and moderate fluid (1,000 cc. or more) ration.

4. There is no relation between protein, salt and water intake.

5. While the normal individual eating a low protein diet tends to have a low blood pressure and a low hemoglobin percentage, the normal person eating a high protein diet has no increased blood pressure and his hemoglobin is normal.

6. The high protein diet has less effect in raising the blood urea nitrogen than has a low fluid intake.

7. People with hypertension do not habitually eat more protein or more salt than normal persons. There is no evidence to show that a low protein diet, followed by a hypertensive subject, will materially reduce the blood pressure provided there is no anemia.

DIVINYL ETHER

A REPORT OF ITS FURTHER USE AS A GENERAL ANESTHETIC

PHILADELPHIA

In 1934 we¹ reported experimental and clinical observations on the use of divinyl ether as a general anesthetic. At that time our experience was based on the use of divinyl ether in 461 patients. We were led to conclude that "from the standpoint of induction, maintenance and recovery the anesthetic is satisfactory.

... Its exact position in relation to the other general anesthetics now being used will have to await a more extensive clinical experience."

The use of the anesthetic has been extended to a number of the clinical departments of the hospital, and in certain of them it has become the anesthetic of choice when general anesthesia is required. The data in this paper have been obtained from 2,675 anesthetizations. This is by far the largest series reported. We believe that it is now possible more clearly to define the usefulness of this substance as an anesthetic agent.

METHOD

In our first series of 461 patients the open drop method was used in about 90 per cent of the patients. In approximately 10 per cent it was administered in conjunction with nitrous oxide and oxygen. In the present series divinyl ether was administered by the open drop method in 2,266 instances (84 per cent) and by the closed method, that is, with nitrous oxide and oxygen, or more usually with oxygen alone, to 409 patients (15 per cent).

We believe that for short anesthetizations the method of administration is unimportant, provided, when the open drop method is employed, the anesthetic is administered through only a few layers of loosely fluffed gauze. For periods of anesthesia exceeding one-half hour it is best that the anesthetic be volatilized with oxygen. This should be done for two reasons; first, the anesthetic is so volatile that a considerable amount of it is lost by evaporation when the open drop method is employed, and, second, our laboratory investigations have convinced us that the use of a plentiful supply of oxygen with the anesthetic greatly reduces the incidence of liver necrosis, at least in the dog.²

With either method the anesthetist must exercise due caution lest he exceed the concentration in the blood necessary for anesthesia. The anesthetic concentration in the blood of man for surgical anesthesia with good abdominal relaxation is approximately 18 mg. per hundred cubic centimeters, while the concentration for extra-abdominal operations when marked muscular relaxation is not required is less than this figure, concentrations of 11 mg. per hundred cubic centimeters having proved satisfactory.

The concentration in the blood necessary for surgical anesthesia is less than that required for chloroform

17. Hawk, quoted by McLester,¹ p. 29.

anesthesia and approximately the same as is necessary when cyclopropane is used.³ The lethal blood concentration in the dog is 68 mg. per hundred cubic centimeters. We do not know what this figure may be in man. However, since the anesthetic concentration in the dog was 28 mg. per hundred cubic centimeters, which is higher than for man, it may be safely presumed that the lethal concentration in man does not exceed that for the dog.

Surgical anesthesia is rapidly and smoothly induced and it is not necessary to push the anesthetic to obtain the desired objective. The rapidity of the recovery from the anesthetic implies that it is rapidly removed from the body and provides a safety factor of no mean importance in so potent an agent.

TYPES OF CASES

In order that the anesthetic might receive a thorough study, it has been used in a wide variety of surgical lesions (table 1).

In the dental cases it has proved a valuable anesthetic and has supplanted the use of nitrous oxide and oxygen in the dental clinic in the Hospital of the University of Pennsylvania. The rapid induction and recovery, with efficient relaxation and minimum of after-effects, has made it the anesthetic of choice in this clinic.

The very low incidence of anoxemia, even for a short period, when divinyl ether has been used, in

TABLE 1.—General Classification of the Patients

Dental	200
"	30
"	1,113
"	178
General and neurosurgical	1,148
Total	2,675

comparison with that observed during nitrous oxide and oxygen anesthesia for dental extractions, has been striking. The recovery from the anesthetic has been just as rapid, if not more so, than with nitrous oxide and oxygen anesthesia.

We have been particularly impressed with the ease with which anesthesia can be maintained when a small piece of gauze is placed over the nostrils. When it is necessary to prolong the period of anesthesia, this is of definite advantage. The rapid recovery and infrequency of postanesthetic vomiting are of real importance in any clinic which has no provision for the temporary bed care of patients.

While it is true that the ophthalmologist, as a rule, prefers local anesthesia, there are times and conditions when general anesthesia is necessary. In the latter group divinyl ether has proved itself to be an ideal anesthetic. It has been very useful in fundus examinations in children and in a variety of ophthalmic operations in which local anesthesia needed reinforcement, or in children in whom cooperation could not be obtained for operations under local anesthetics. The ease with which the anesthetic may be administered through a small piece of fluffed gauze obviates the necessity of a mask, as is often required when nitrous oxide and oxygen are used.

The rapid, smooth induction is not attended by the struggling which so frequently is encountered during the induction of diethyl ether anesthesia in children.

In our earlier series one instance of overconcentration of the anesthetic occurred, with rapid recovery after cessation of the anesthetic. In the present series no such complication was encountered.

In the field of otolaryngology divinyl ether has been widely used by us. It was used as the sole anesthetic in a series of tonsillectomies. In these it was the opinion of the operator that oozing from the tonsillar bed was greater than when diethyl ether was used. The oozing, while not alarming in any instance, was such as to be annoying during the removal of the second tonsil. It is for this reason that it is not now used as a routine for tonsillectomy. It is, however, now being used as a routine for the induction of general anesthesia for this operation in this hospital.

It is the opinion of both anesthetists and clinicians that the induction is more rapid and smoother than when nitrous oxide and oxygen is used as the preliminary anesthetic. Induction is much more rapid than when diethyl ether is used, and efficient relaxation of the masseter muscles is obtained at a much earlier period. The excitement period, so frequent in children when diethyl ether is used throughout, has been practically eliminated.

Divinyl ether has been used satisfactorily for mastoid operations, myringotomy, suppurative cervical adenitis and harelip operations. For myringotomy, in which only a very short period of anesthesia is required, it has practically supplanted all other anesthetic agents. A small amount of the anesthetic can be carried to the patient's bedside and the operation completed before the initial stages of diethyl ether anesthesia could have been induced. Furthermore, no apparatus such as is necessary when nitrous oxide and oxygen are used is required.

It has been used for a variety of orthopedic procedures including tenotomy, exposure and manipulations of joints, and the reduction of fractures. The rapidity with which relaxation can be obtained makes it exceedingly useful in the manipulation of bones and joints, especially when repeated anesthetizations may be required. Patients have not objected to repeated anesthetizations, the postanesthetic sensations on the whole being very pleasant. In painful dressings in children, short periods of anesthesia may change the morale of the entire ward. When restriction of motion of a joint results from prolonged immobilization, the use of the anesthetic during early manipulation results in a very grateful patient.

The general surgical procedures in which the anesthetic has been used are too varied to enumerate. They include thyroidectomy, rib resection, a large number of abdominal procedures, herniorrhaphy, hemorrhoidectomy, the reduction of fractures, and operations on the general soft parts of the body.

In many of these conditions it has no superiority over other anesthetics now available. For short operations in which rapid induction and recovery are desired, it is exceedingly useful. In those operations in which greater relaxation is required than that afforded by the anesthetic being used, divinyl ether is most helpful. For the fluoroscopic reduction of fractures, at all ages, it has become the anesthetic of choice. The rapidity with which relaxation is obtained is of real value in these cases. This is especially true when it is remembered that many of these patients have had no special preparation for anesthesia and frequently have ingested food a short time before anesthetization.

3. Waters, R. M., and Schmidt, E. R.: Cyclopropane Anesthesia, J. A. M. A. 103:975 (Sept. 29) 1934.

In the surgical outpatient department it has proved so efficient that nitrous oxide and oxygen are no longer used when a general anesthetic is required. In the incision and drainage of abscesses, the repair of lacerations of the soft parts, and for the reduction of ambulatory fractures, it has proved exceedingly efficient. It is the opinion of the staff of the surgical outpatient department that the rest required following anesthesia is approximately one-fifth as long as when nitrous oxide and oxygen are used.

AGES OF THE PATIENTS

The youngest child in this series was 15 months old and the oldest patient 75 years old. A child of 19 months was anesthetized for one hour and twenty minutes. During the entire period maintenance was smooth and at the completion of the operation recovery occurred in less than four minutes.

In hypertensive aged individuals and in patients with cardiac disease it has proved useful, for there is no tendency for the anesthetization to be attended with further elevation of the blood pressure, as so frequently occurs in nitrous oxide and oxygen anesthesia. Every age group over 1 year has been anesthetized. There is no age contraindication to its use.

LENGTH OF ANESTHESIA

In table 2 are given the data on the duration of anesthesia in the 2,675 anesthetizations.

It will be seen that nearly 85 per cent of the patients anesthetized received the anesthetic for short periods—up to thirty minutes. However, 15 per cent of the patients were anesthetized for from thirty to sixty minutes. One patient was anesthetized for two hours, one for two and one-half hours, and one for four and one-half hours. In the longer anesthetizations oxygen was nearly always used with the divinyl ether.

We have exercised caution in the use of the anesthetic for long periods because of the possible danger of liver necrosis. When the anesthetic period exceeded thirty minutes we have in certain instances changed to another anesthetic agent. This has been done to provide maximum safety, although we have come to believe that, properly administered, the time limit need not be so rigidly adhered to. In the entire series we have observed no serious untoward results. The group up to thirty minutes consists of 2,257 patients and is large enough for us to state that, properly administered, the anesthetic is safe for this period.

We have frequently resorted to its use when operations under spinal anesthesia have extended beyond the time of spinal anesthetization. It has also been used during the closure of abdominal incisions when the relaxation afforded by nitrous oxide and oxygen was insufficient for secure closure of the wound. For this purpose it is ideal.

Forty-one patients have been anesthetized on more than one occasion during a single admission. Twenty-three patients were anesthetized twice, ten patients three times, four patients four times, and four patients five or more times during a single admission. In not a single instance did the repeated anesthetization result in any untoward complication.

ANESTHESIA

With extended experience we can well repeat what we said in our earlier paper. The stage of induction with divinyl ether is short, so short in fact that it is rare to observe analgesia without loss of consciousness,

except for the briefest interval. We have become accustomed to the rhythmic oscillation of the eyeballs that is observed frequently in light third stage anesthesia with this agent.

Laryngeal irritation is practically never observed, but we have had three instances of tight masseter spasm which was disturbing until an airway was introduced. This has always been observed during the early stages of anesthesia. It is not peculiar to divinyl ether anesthesia, since we have observed this complication with a variety of anesthetic agents.

In our earlier series we reported a stage of excitement in 2 per cent of our patients. In the present series, undue excitement lasting more than a few moments was present in twelve patients, which is less than 0.5 per cent. We believe that the reduction in the incidence of excitement is due to increased experience with the anesthetic, which permits of more rapid induction. Administered as it should be by experienced anesthesiologists, the rapidity of induction prevents a prolonged stage of excitement except in a very few.

Excessive mucus was present in nineteen patients, even though in nearly every instance the patient had received atropine sulfate prior to the anesthetization. The incidence of this annoying complication is so low, however, that it is of little consequence.

There have been six instances of marked cyanosis which was relieved either by the use of oxygen or

TABLE 2.—Length of Anesthesia

Up to 30 minutes.....	2,257
From 30 to 45 minutes.....	316
From 45 to 60 minutes.....	92
From 60 to 90 minutes.....	7
More.....	3

by reducing the amount of the anesthetic used. There have been no major respiratory complications in the series, although there have been several instances of postanesthetic bronchitis. We are again impressed with the absence of respiratory complications following divinyl ether anesthesia. In our first series we believed that the low incidence of postanesthetic respiratory complications was due to the selection of cases and to the unusual care incident to the first tests with a new anesthetic. These factors do not apply nearly so closely to the present series. It would seem that anesthesia with this substance is remarkably free from postanesthetic pulmonary sequelae.

The relaxation that has been obtained has been good. There have been several instances in which the surgeon believed the relaxation unsatisfactory, but in each instance the subsequent administration of diethyl ether did not afford greater relaxation. Every anesthetist and surgeon of experience has seen patients in whom it was difficult to obtain relaxation regardless of the anesthetic that was used. The fact that divinyl ether has practically supplanted every other anesthetic in the fluoroscopic reduction of fractures in the Hospital of the University of Pennsylvania means that the surgeons of the hospital are satisfied with the relaxation that the anesthetic affords.

Recovery from the anesthetic even after prolonged anesthesia is rapid when compared with diethyl ether or chloroform. It is, as a rule, more rapid than after nitrous oxide and oxygen anesthesia for a comparable period. The recovery is usually smooth, and is only rarely accompanied by any excitement. The postan-

thetic sensations are nearly always pleasant, so that patients have had little fear of subsequent anesthetizations.

Vomiting more than once during the period of recovery and immediately thereafter occurred in fifty-four patients. When all patients vomiting a single time, which included the simple eructation of mucus, are included, the total number was 173, which is slightly more than 6 per cent. Since the anesthetic was administered practically as a routine in the surgical outpatient department when a general anesthetic was required and on many other occasions when there had been no control of diet prior to anesthetization, the incidence of vomiting must be considered low.

The urine was not examined in many of these patients after operation, but in those in which this was done, which is in excess of 600, there was not a single instance in which the urinary changes suggested that the anesthetic was a renal irritant.

Three patients in this series of 2,675 anesthetizations died within one week following operation. In each instance an autopsy was obtained and the death was in no manner ascribable to the anesthetic. Although liver necrosis in the human being can occur with divinyl ether anesthesia, we have not encountered it in this series. We have avoided using it on patients with known extensive hepatic derangement. If our experience is a criterion, we feel safe in stating that post-anesthetic liver necrosis will not prove of any consequence when the anesthetic is properly administered for periods of anesthesia not exceeding one hour.

COMMENT

From our experience in a large number of patients anesthetized with divinyl ether we feel that the statement made by Leake and Chen⁴ in 1930 that substances possessing the pharmacologic and chemical characteristics of diethyl ether and ethylene would be interesting anesthetic agents has been further substantiated. The hope that divinyl ether would prove to be the ideal anesthetic agent has not materialized. By the ideal anesthetic we mean one that would supplant all known general anesthetic agents. Surely such a substance does not now exist. However, divinyl ether possesses many of the characteristics which the ideal anesthetic agent must offer.

Anesthesia can be rapidly induced, and recovery is equally rapid. The induction is more rapid than with diethyl ether or with nitrous oxide and oxygen. The incidence of excitement is considerably less than with either of these agents and the recovery is as a rule much more rapid. Minute for minute of maintenance of anesthesia, the recovery from divinyl ether requires only a fraction of the time necessary for diethyl ether.

The incidence of untoward complications in our series following the use of this substance is low. In this hospital where in the general, neurosurgical and urologic services a careful record has been kept for the past fourteen years of the major complications, the incidence of postoperative complications has been lower than with diethyl ether, nitrous oxide and oxygen or spinal anesthesia. It must be admitted, however, that it is difficult to compare data from one anesthetic with another without carefully considering the condition of the patient prior to anesthetization and the indications that led to the selection of one anesthetic over another.

We feel safe in recommending divinyl ether as a general anesthetic for the extraction of teeth, the reduction of fractures, the manipulation of joints and a large number of surgical procedures which do not require prolonged anesthesia but which may require any degree of relaxation. It has been found to be safe in a very wide range of ages and in patients with severe myocardial disease. Rapid induction, smooth maintenance and rapid recovery can be expected and obtained. Post-anesthetic vomiting is infrequent, and postoperative pulmonary complications in our experience are rare.

Reports from other clinics on the use of divinyl ether for anesthesia are now available (Bourne,⁵ Shipway,⁶ Bätzner,⁷ Killian,⁸ Dörfel,⁹ Marvin,¹⁰ Oehlecker¹¹). Bourne has had a fairly extensive experience with divinyl ether anesthesia in obstetrics, a field in which we have had no experience. He concludes that "divinyl oxide is a very suitable anesthetic for employment in obstetrics. It permits of rapid application, equally rapid recovery, and a satisfactory maintenance of any desired degree of narcosis with minimal danger to mother and child."

Dörfel's⁹ experience in the Surgical Polyclinic of Leipzig is similar to that of the surgical outpatient department of our hospital. He too found the anesthetic exceedingly useful because of the rapid induction and recovery and the infrequency of postanesthetic vomiting.

Bätzner⁷ concluded from his experience that the anesthetic was as safe as diethyl ether, provided as efficient relaxation as chloroform, and was as rapid in its induction as the sodium salt of *n*-methyl-cyclohexenyl-methyl barbituric acid and as rapid in recovery as nitrous oxide and oxygen. Oehlecker¹¹ found it to be advantageous in small children.

In the several instances in which liver necrosis has occurred¹² after anesthetization, it has in each instance been found to be associated with prolonged use, excessive dosage or coincidental anoxemia. Contrary to Leake's opinion, we believe that liver necrosis may occur following divinyl ether anesthesia over a long period when every precaution to prevent anoxemia has been taken. We have been able to produce in the dog a degenerative lesion in the liver following diethyl ether anesthesia when the available oxygen was reduced in concentration but 5 per cent below that found in air. Chloroform is still being widely used even though its tendency to produce liver necrosis greatly exceeds that of divinyl ether. While chloroform will produce liver necrosis in the dog following one hour of anesthesia, it requires three hours of divinyl ether to produce liver necrosis in the dog, and even then the extent of the necrosis is not so great. While it is more toxic to the liver than diethyl ether, it is not as toxic as chloroform.

This fact should not prevent the use of an anesthetic which possesses many of the qualities that are desired in an anesthetic agent. It does, however, lead us to state that it should be used as a rule for operative

procedures of short duration in which rapid induction and recovery and a minimum of postanesthetic effects are desired.

SUMMARY

1. Divinyl ether has been used in 2,675 anesthetizations in a number of clinical departments, for a wide variety of lesions requiring anesthesia, principally of the shorter type.

2. Anesthesia is rapidly induced and easily maintained, and recovery is rapid. Muscular relaxation is excellent.

3. The postanesthetic complications in our cases have been low.

4. No instance of liver necrosis has been observed in our patients, but this was guarded against because this agent is more toxic than diethyl ether although less toxic than chloroform.

5. For short anesthetizations the anesthetic can be administered by the drop method, but for periods of anesthesia exceeding forty-five minutes the simultaneous administration of oxygen is advisable. Only a few of our patients were anesthetized for longer than forty-five minutes.

6. For a wide variety of operative procedures of short duration we believe that divinyl ether is a most useful anesthetic substance.

THE USE OF UREA IN THE TREATMENT OF INFECTED WOUNDS

HALL G. HOLDER, M.D.

SAN DIEGO, CALIF.

AND

EATON M. MACKAY, M.D.

LA JOLLA, CALIF.

Urea in strong solution has a peculiar property of being able to "dissolve" proteins and protein substances. First noted by Spiro,¹ this lytic property was not thoroughly examined until discovered independently by Ramsden.² This "dissolving" of proteins occurs in neutral solutions or solutions of varying degrees of alkalinity or acidity, and since urea is a relatively inactive substance it occurred to one of us that it might be useful in wound therapy for the removal of mucus and other exudates, encrustations and necrotic tissue. Since commencing its use we have found that other investigators have already utilized it for the same purpose but for a different reason. Symmers and Kirk³ more than twenty years ago, as a result of certain bactericidal properties they observed in urea solutions, used this chemical for the dressing of wounds, with excellent results. Millar⁴ in a short note several years ago suggested the use of urea to suppress the foul odors of sloughing cancer. Foulger and Foshay,⁵ impressed with the bactericidal action of urea, have also used it for treating infected wounds of various sorts with good results. Despite these favorable reports, urea therapy in the treatment of wounds has not attained any wide usage.

From the Scripps Metabolic Clinic, La Jolla, and the San Diego General Hospital.

5. Foulger, J. H., and Foshay, Lee: The Antiseptic and Bactericidal Action of Urea, *J. Lab. & Clin. Med.* **20**: 1113 (Aug.) 1935.

Our successful experience with urea therapy of infected wounds prompts the present report of the use of this therapeutic agent. We have used both the solid crystals and saturated solutions. Formerly synthetic urea of German origin was utilized. More recently synthetic urea has become available in this country (Du Pont) for the first time and can be purchased in 100 pound sacks at from 5 to 10 cents per pound, depending on the quantity purchased. It requires no further preparation for medicinal use.

So far a total of 139 cases have been treated with urea. These may be classified in the broad groups shown in the accompanying table. In no case did the application of urea in solution or as the crystals have any deleterious effects. Although in a few cases the application of urea did not appear to influence the course of the condition, the clinical impression was gained that not only was urea therapy efficient but it was far more successful than the common therapeutic agents used for infected wounds. There are so many factors in each case that it is very difficult to determine the relative efficacy of various medications. These case differences make controls impossible except in the very broadest sense. However, in many of the cases the good results were startling both in long standing lesions that had resisted ordinary treatment and in more recent pathologic conditions in which the result exceeded the usual expectations with diluted solution of sodium hypochlorite or other agents. The best results were obtained with the chronic ulcers, although most of the infected wounds became healed more quickly than can usually be expected. The less positive results for the "infectious group" may have been due to the greater cautiousness with which the urea was used in these cases. This agent cannot be used sparingly if successful results are to be expected. Several cases of osteomyelitis responded poorly to the treatment, but this may have been because the crystals were used and the exudate may have been insufficient to allow it to penetrate. It is obvious that the solution is the application method of choice in any condition in which a sinus or

fistula is involved. Several typical results of the use of urea in individual cases are presented here:

CASE 1.—J. S., a youth, aged 17, injured the lower third of the left tibial crest in a football game and a trophic-like ulcer developed on the skin. Prolonged treatment with several commonly employed bactericidal agents failed to be effective, and the margin of the ulcer became further undermined with progressive enlargement. Ten days' application of urea crystals eliminated all infection, giving a healthy granulating base which was successfully grafted with Thiersch grafts. Thio-urea (8 per cent) was used as a wet dressing with 90 per cent successful growth of grafts and complete epithelization. The patient was discharged home cured twenty-one days from the onset of treatment.

CASE 2.—N. V., a man, aged 33, struck the anterior portion of the right leg midway between the knee and the ankle on a tent stake one month prior to admission and caused a slight abrasion. The usual methods of treatment for three weeks were not productive of healing and five days before admission to the hospital the unhealed area became sore and inflamed and this increased in severity. On the first examination the lesion was about the size of a half dollar (30 mm.) with undermined skin edges, a gray sloughing sore and an extensive surrounding area of cellulitis. The purulent discharge possessed a very foul odor. Initial treatment consisted of complete bed rest, elevation of the extremity and continuous hot saturated wet dressing of magnesium sulfate from the foot to the groin. This treatment was continued for four days with no improvement but rather a progressive extension of the ulceration of approximately one-fourth inch (6.4 mm.) daily. The wet dressings were discontinued and Dakin's technic was instituted for the following three days with no improvement and gradual extension of the tissue destruction, so that the ulcer area now measured about 5 by 6½ inches (13 by 16 cm.). At this point the area was packed once daily with urea crystals and, following the second application, definite clinical improvement was noted. Four days thereafter, or six days from the commencement of treatment, the necrotic tissue had completely disappeared, leaving a clean granulating base in which there were scattered islands of epithelium. Application of wet dressings of thio-urea for thirteen days produced complete and satisfactory healing without the necessity of skin grafting.

CASE 3.—M. C., aged 15 years, was struck in the left ankle with a rock and sustained a slight skin abrasion over the lateral malleolus and what was thought to be a sprain. X-ray examination at the time of the accident was negative for bone injury. The ankle gradually improved during the following thirty days and then progressively became worse, the symptoms extending over a period of six months. A roentgenogram taken at this time showed an extensive osteomyelitis involving the distal third of the fibula. Operation was performed and the involved bone removed; the wound was packed with petrolatum gauze and a plaster cast applied. On the fifth postoperative day a window was cut in the cast over the operative incision, the petrolatum packing was removed and the wound packed with urea crystal-picric acid mixture. Complete healing occurred in two months; the patient recovered entirely and was walking with no loss of function in three months. A check-up x-ray examination showed complete and satisfactory regeneration of the bone in the involved area. Many other more extensive and chronic cases of osteomyelitis have responded just as satisfactorily in the presence of adequate drainage. It was necessary in a number of these cases to use urea in saturated solution irrigated through catheters or Dakin's tubes placed in the multiple sinuses.

CASE 4.—T. S., aged 72, had a carbuncle which on admission, Nov. 1 1935, involved the entire intrascapular region. The temperature on admission was 103 F. The patient was irrational and toxic and appeared very ill. Urinalysis showed a trace of albumin and sugar, hyaline casts and an occasional white blood cell. A blood count revealed red blood cells 4,200,000 with 78 per cent hemoglobin, white blood cells 8,000 with polymorphonuclears 80 per cent, lymphocytes 18 per cent and monocytes 2 per cent (poor response). The carbuncle in the shoulder was opened with cruciate incisions with the actual cautery; the flaps were well undermined to the healthy tissue and the wound was packed with urea crystals. Mild glycosuria was controlled and the patient was given the usual supportive treatment. The following day the temperature was 99.6 F., and the patient was comfortable. The third day the temperature was normal and remained so for the remainder of convalescence. The wound was clean, with healthy granulation tissue in three weeks. Thio-urea was then applied with complete healing, without the necessity of skin grafting, on the thirty-sixth day (five weeks) after operation.

CASE 5.—J. P., aged 14, accidentally sustained a shotgun wound of the right upper thigh and buttocks. The original defect and tissue loss measured about 6 inches (15 cm.) in diameter. Débridement was done under general anesthesia; dirt, débris, shot and devitalized tissue were removed and tetanus antitoxin was given. The wound edges were closed as well as possible and the remaining central cavity was packed

with urea crystals. A clean granulating wound was obtained in two weeks and, following further application of thio-urea, complete healing without the necessity of skin grafting obtained in another two weeks. The patient was ambulatory with no loss of function. (This was a remarkable result considering the defect.)

There appears to be no condition that the application of urea might possibly aid in which it is contraindicated. Urea is practically nontoxic and harmless in any reasonable quantity. For this reason and because of its cheapness it may be used liberally. Some antiseptic agents, particularly the various chlorine solutions, are unstable. Urea in the dry state is permanently stable and in strong solution remains unaltered for any length of time that one may wish. Even in contact with an open wound, urea retains its activity and is undecomposed. With urea therapy the danger of burning the surrounding skin is avoided. Urea appears to be without effect on living tissue, although in strong solution or as a crystal pack it may be rather painful on the wound or on mucosal surfaces. The best evidence that it is innocuous rests in the fact that even in gross quantities it does not cause necrosis of Thiersch grafts, an observation that was also noted by Symmers and Kirk.³ The most obvious virtue of urea is the removal of the foul odor of suppurating wounds, and this without replacing one odor by another, as in the case of many deodorants.

The use of urea that we have discussed here should not be confused with the recent report of Robinson⁶ reviewing the results of a number of practitioners in using a 2 per cent urea solution in the treatment of chronic and purulent wounds. This concentration of urea is too low to have any appreciable "solvent" action and we have been unable to obtain any evidence that urea directly stimulates healing, as this author seems to suggest. This investigator is of the opinion that urea, like allantoin, may be a metabolic product of living maggots which contributes to the healing action of maggot therapy.⁷

Possibly a better view, particularly in the light of critical surgical experience, is that therapy with maggots owes its success solely to the "scavenger action" of Baer that is produced by their ability to dissolve and digest dead tissue and débris.⁸ In this connection the results with 2 per cent urea solutions are more explicable. All dead tissue tends to undergo autolysis, and Ramsden² showed long ago that 2 per cent urea has a marked effect in promoting the digestion of fibrin by proteolytic enzymes. In the concentrations of urea that we have used, on the other hand, we know that enzyme activity is definitely inhibited. For practical purposes we are doing chemically with strong urea solutions what normal tissue enzymes may do to some extent or what maggots may do in localized areas. The effect on healing in all cases is probably entirely passive; i. e., the procedures have no direct influence on cell growth or epithelization but only aid this to proceed normally by removing dead tissue, dried secretions and other hindrances. In addition, as we have pointed out, strong urea solutions have some bactericidal effects and an even more definite bacteriostatic influence, which is most desirable in infected wound therapy.

7. Baer, W. S.: The Treatment of Chronic Osteomyelitis with the Maggot. *J. Bone & Joint Surg.* 13: 438 (July) 1931.

8. Messer, F. C., and McClellan, R. H.: *J. Lab. & Clin. Med.* 20: 1219 (Sept.) 1935.

Two⁹ of the three previous users of urea for wound therapy were prompted to use it because of its bactericidal effect. Ramsden² originally noted that in a saturated urea solution no putrefaction ever takes place. Péju and Rajat¹⁰ and later Wilson¹¹ noted the influence of urea on bacterial growth. Foulger and Foshay⁵ recently added to these data. In experiments to be presented elsewhere we have found that urea solutions of less than 15 per cent are not uniformly bacteriostatic and that those of less than 30 per cent not usually bactericidal. In the case of the common pyogenic organisms, the staphylococcus is the most resistant to urea action. Our experience has led us to conclude that urea in any concentration is not a really good germicide and that, although most certainly a contributing factor, bactericidal activity is not the chief influence in the usefulness of this substance for wound therapy.

With the end in view of giving urea solutions a more marked destructive action on bacteria, the addition of various substances to these solutions is now being examined. Calcium picrate¹² has been suggested for the treatment of osteomyelitis. "Urea picrate" is a loose compound and is now being tried out in combination with urea solutions. Phenol has been used to irrigate filthy chronically infected bladders. This acid forms an unstable compound with urea, and we are now investigating "urea phenolate" in strong urea solutions for this purpose. The phenol tends to reduce in some degree the pain incident to the presence of the strongly hypertonic urea solution on the mucosa. Many other combinations could be suggested and should be tried out.

Robinson,⁶ as we have noted, is apparently of the opinion that urea directly stimulates healing. It is our opinion that this is not the case either in the mechanism of maggot therapy or with strong urea solutions. It seems more reasonable that in both cases conditions deterrent to healing are simply removed. However, there are certain compounds, notably those with the sulfhydryl group such as cysteine, thioglycerol and thiophenol, which appear definitely to have the ability to increase the rate of cell division and particularly epithelization. There seems to be no reason why these cannot be used in conjunction with urea solutions. In particular we have given thio-urea some trial and this gives promise of increasing the rate of wound healing quite apart from the more indirect effects of strong urea applications.

SUMMARY

The application of gross quantities of urea crystals or of strong to saturated aqueous urea solutions to infected wounds of various types definitely hastens healing and is frequently efficacious when other therapeutic agents are ineffective. Urea application is cheap, does not irritate the surrounding normal tissue and practically obliterates all odor arising from an infected wound. The mechanism of urea therapy is probably in part by virtue of the bactericidal effect of strong urea solutions but chiefly through the solvent action on proteins, which leads to a removal of the debris, encrustations and dead tissue, which mechanically and by harboring bacteria are usually the chief deterrents to normal healing.

Clinical Notes, Suggestions and New Instruments

ALLERGY TO DYES

CONTACT DERMATITIS FROM EASTER EGG DYE—ASTHMA AND
URTICARIA FROM METAPHEN

LEO H. CRIEP, M.D., PITTSBURGH

The type of manifestations that may be found in individuals allergic to dyes depends largely on the sensitive tissue. If the allergy is limited to the epidermis the lesion is contact dermatitis, while if the dermis is involved urticaria results. If the allergy is in the mucous membrane of the bronchi and bronchioles, bronchial asthma develops.

The following is an account of these various allergic manifestations occurring in two dye-sensitive patients:

REPORT OF CASES

CASE 1.—*Contact dermatitis due to Easter egg dye.* A child, aged 4 years, presented a history of flexor eczema (dermatitis involving the elbows, knees, face and neck) since early infancy. There was a strong family history of allergy. The blood showed an eosinophilia. The allergic survey and intradermal tests revealed sensitivity to several foods. Allergic treatment resulted in complete disappearance of eczema. Six months later the patient developed an extensive vesicular dermatitis involving the hands, forearms and face. The history elicited the information that the child had been painting Easter eggs with dyes that come put up in the form of matches. Investigation revealed that the colors used in these matches are oil blue G (alkyl aryl amino anthraquinone); oil red N-1700 (diazo dye belonging to the tolyl azo-zylyl azo-naphthol family); oil orange 7078 (monazo dye of the phenyl azo-naphthol group) and oil yellow. In addition, there is a small amount of ordinary commercial wax and sulfonated castor oil.

Intradermal tests with these dyes were negative, as was to be expected, since the allergy in this patient is limited to a sensitivity of the epidermis only. Patch tests, however, gave a positive reaction to red and orange but no reaction to the wax, castor oil or other dyes. Local symptomatic treatment and absolute avoidance of these dyes brought about complete relief.

CASE 2.—*Urticaria and bronchial asthma due to metaphen.* A man, aged 46, was first seen five years before, when he gave a history of bronchial asthma of ten years' duration. Occasionally there would be a mild attack of urticaria. There was no family history of allergy. Epinephrine would give him symptomatic relief. A blood smear showed an eosinophilia. Allergic survey and intradermal tests revealed the presence of sensitivity to several inhalants (feathers, orris root and the like) and foods. Allergic treatment rendered him completely symptom free for about two years, after which period he returned to the clinic and gave the following history:

While working in the mill he bruised his finger, the skin being only slightly abraded. He presented himself at the emergency hospital, where it was dressed after the application of metaphen. Within a half hour after this application a very severe attack of asthma developed, which lasted practically the entire night in spite of the administration of repeated injections of epinephrine. A week later, when the finger was dressed with untinted metaphen, no reaction occurred. This was repeated two days later with the same results. At this time scratch tests and intradermal tests with both the tinted and the untinted metaphen were negative, but following the tests with the tinted metaphen, and ranging from a half hour to three hours after the tests were performed, a very severe attack of asthma developed which lasted practically the entire night. Patch tests performed with both the tinted and the untinted metaphen were negative. After the patch test was performed with tinted metaphen, an attack of asthma developed. No such attack resulted from the patch test performed with the untinted product. Information received from the Abbott Company states that the dye employed in metaphen is orange I. The dye is also called tropeolin 000 No. 1 and alphanaphthol orange. Chemically it is sodium azo alphanaphthol sulfanilate ($C_{16}H_{11}N_3O_2SNa$). Scratch tests and intradermal tests were then performed with

the dye alone (dilutions of 1:1,000 and 1:100) and a negative skin reaction occurred. Several weeks later, after all symptoms disappeared, an area on the arm the size of a silver dollar was painted with the orange dye. Two hours after the arm was painted a severe attack of asthma developed accompanied by generalized hives. These lasted over a period of about ten hours, necessitating the frequent administration of epinephrine. The procedure was repeated with exactly the same results several days later. It is interesting that when his left arm was painted with the orange dye, large hives and a massive swelling accompanied by itching, which lasted for a period of forty-eight hours, developed on the right arm at the point where the scratch test was done several days previously with the tinted metaphen. Complete avoidance of exposure to the tinted metaphen resulted in complete relief.

The allergy presented by this patient is one that involves a sensitivity of the dermis (urticaria) and the mucous membrane of the bronchi and bronchioles (bronchial asthma). It illustrates the nonantigenic nature of dyes as shown by the absence of demonstrable antibodies (reagins), for this patient gave a negative scratch and an intradermal skin test as well as a negative passive transfer to the dyes to which he is no doubt allergic.

LAUGHLIN'S TEST FOR THE SERODIAGNOSIS OF SYPHILIS

F. H. ROBINSON, M.D., AND GEORGE M. STROUD, B.S., DURHAM, N. C.

The serologic diagnosis of syphilis is at present complicated, time consuming and expensive. A rapid, cheap and reliable method of diagnosis is highly desirable. Laughlin¹ has recently described such a method and it is our purpose in this brief communication to report on its use in 1,000 serums taken in a routine manner from hospital patients. In Laughlin's test a drop of reagent is added to a drop of serum or spinal fluid on a glass slide, which is then tilted repeatedly and observed at frequent intervals in an indirect light. The reagent is prepared by adding tincture of benzoin compound, cholesterol, scarlet red and physiologic solution of sodium chloride to an alcoholic extract of beef heart. The reader is referred to the original communication for the exact details of preparation. A positive reaction is recognized by the macroscopic appearance of coarse red particles which rapidly increase in size, whereas when the reaction is negative the fluid remains homogeneous.

Laughlin compared the results obtained by his test with those of the Wassermann and Kahn tests on four hundred serums and found his results to be in agreement with the Wassermann test in 98 per cent of serums and with the Kahn test in 99 per cent. He made the same comparison with the serums of 118 patients receiving antisyphilitic treatment and found that his test agreed with the Wassermann test in 93.5 per cent and with the Kahn test in 97 per cent of the cases.

When the three tests were done simultaneously on 1,000 serums in our laboratories it was found that the Laughlin test was in accord with the Wassermann test in 93 per cent of serums and with the Kahn test in 97 per cent, thus confirming with surprising exactitude Laughlin's results. In this series of 1,000 cases the reagent employed was prepared by us according to Laughlin's directions. In an additional series of fifty serums Laughlin's reagent was supplied by the Lederle Laboratories, and the results obtained were in accord with simultaneous Wassermann and Kahn tests in every instance. We have found the Laughlin test equally reliable when cerebrospinal fluid is tested.

This test offers a simple and rapid quantitative estimation of serologic positivity because the degree of positivity is read in terms of seconds required to react with the reagent. Therefore this test is of great value in following the response of serums of patients under treatment.

Some experience and skill are required in the balancing of Laughlin's reagent, for it must be so adjusted that a positive reaction is given with serums showing a one plus Wassermann reaction and no reaction to serums which are negative to the Wassermann test. This adjustment is readily made. Because

1. Laughlin, G. F.: A Rapid Test for Syphilis. *Canad. M. A. J.* 33:179-183 (Aug.) 1935.

of its simplicity and speed the test is useful in testing donors for emergency blood transfusions, as a rapid preliminary test for suspected syphilitic meningitis and for emergency work in the outpatient clinic.

CONCLUSIONS

1. The Laughlin test is a simple, practical and reliable test for syphilis.
2. The degree of positiveness can be read in terms of seconds required to react with the reagent.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION
OF THE FOLLOWING REPORTS.
HOWARD A. CARTER, Secretary.

ANNUAL MEETING

The Council on Physical Therapy held its annual meeting January 8 and 9. The following members were in attendance: Drs. W. W. Coblenz, John S. Coulter, A. U. Desjardins, W. E. Garrey, Frank H. Krusen, Harry E. Mock, Frank R. Ober, Ralph Pemberton, H. B. Williams, Olin West, Morris Fishbein and Mr. Howard A. Carter.

Dr. Harry E. Mock was reelected chairman, and Dr. W. E. Garrey was elected vice chairman to take the place of Dr. F. J. Gaenslen, who resigned because of illness and the news of whose death came as this report was being prepared for publication.

Dr. Gordon Heyd, President of the American Medical Association, and Dr. Rock Sleyster, Chairman of the Board of Trustees (who were attending the meeting of the Board of Trustees at the same time) gave personal greetings. The members of the Council expressed their appreciation for the enlarged facilities recently made available to them at headquarters.

CHANGES IN MEMBERSHIP

There has been a change in the personnel of the Council in the past year. Drs. George M. MacKee and Robert B. Osgood have resigned. Dr. Osgood resigned because of other more pressing duties, and Dr. MacKee was obliged to curtail his activities. Dr. Frank R. Ober was appointed to fill the vacancy left by Dr. Osgood, Dr. George C. Andrews to fill the vacancy left by Dr. MacKee, and Dr. Frank Dickson to take the place of Dr. Gaenslen. The personnel remains at twelve.

RESEARCH GRANTS

Grants in aid of research are awarded to those persons who demonstrate that they have a problem of merit. Accomplishments of those receiving such grants were looked on with satisfaction. However, the Council felt that there may be more physicians and investigators working on physical therapy problems desiring aid, and it was believed that announcement should be made in scientific journals concerning the availability of these grants of limited sums.

ULTRAVIOLET GENERATORS

In view of the progress that has been made by the Council on Foods in the consideration of vitamin D milks and fortified vitamin D foods and the progress made by the Council on Pharmacy and Chemistry in the consideration of vitamin D concentrates, it was the opinion of the Council on Physical Therapy that the standards for the acceptance of ultraviolet generators should be revised.

EDUCATIONAL ACTIVITIES

The Council expressed its approval of the work of the Committee on Education of the Council and also of the activities of the Consultants on Education who have been aiding in the promotion of physical therapy among practicing physicians. In the opinion of the Council, the tremendous inertia caused by the indifference of the profession to the practice of physical therapy, which existed eleven years ago when the Council was established, has been largely overcome, and resistance at the present time is merely passive. The Council felt that it was important to get in contact with young physicians and undergraduate students in medicine. It was gratifying to learn that many of the younger physicians are specializing in the field

physical therapy for the purpose of taking over departments of physical therapy in schools of medicine. The Council felt that postgraduate instruction in physical therapy might well be carried on under the auspices of the graduate schools of medicine. The following Consultants on Education were reelected: Dr. Bernard Fantus, Dr. A. J. Kotkis, Dr. Richard Kovács and Dr. Franklin P. Lowry. Dr. William H. Schmidt was appointed to take the place in Pennsylvania vacated by Dr. Krusen.

The Council believed that the time was about due for an investigation of spas, sanatoriums and similar health resorts and that this work should be carried out under the direction of the Council on Medical Education and Hospitals.

Suggestions for experiments in physics, bearing on subjects of interest to medical students, the Council decided might well be prepared and distributed to college teachers of physics.

CONSIDERATION OF SHOES

Progress has been made in the consideration of shoes. The preparation of just specifications and requirements to be met was found to be more difficult than was originally expected. This accounts for the delay in reports on shoes submitted to the Council.

LIMITATIONS OF SHORT WAVE DIATHERMY

Much of the work of the Council the past year has been confined to the consideration of so-called short wave diathermy machines. In view of the deliberations, the Council believed it was justifiable to state, based on the present available evidence, the following conclusions:

1. There is no specific biologic action of high frequency currents.
2. There is no specific bactericidal action.
3. The therapeutic effect is due to the heat produced.

Elaborating on these three conclusions, the Council felt that the general practitioner should understand that when he buys a short wave diathermy machine he is simply purchasing an apparatus capable of producing heat. In the light of available evidence, it has absolutely no other specific action. The Council felt that, if this point was understood by the physician in general practice, he might hesitate before purchasing an expensive apparatus, because simpler mechanical means for the production of heat are available and as efficacious in many cases. For the specialist in physical therapy having a sufficient number of cases, the expense of a short wave diathermy machine might not be so important.

The question arose in the minds of the Council whether there was too much emphasis being placed on machine therapy. It was pointed out that the Council went on record several years ago to the effect that physical therapy consists of 90 per cent intelligent handwork which may be accomplished by heat, massage and exercise, and 10 per cent machine therapy. The short wave diathermy machine, for example, is a useful therapeutic agent, but in the light of the present day evidence its therapeutic effect is that of heat and heat only. The Council reaffirmed its stand to continue the consideration of all short wave machines submitted by the methods that have been followed during the last two years. If only minor changes have been made in accepted units, the Council decided that these alterations may be dealt with independently.

RADIO INTERFERENCE

Interference with radio communication by short wave diathermy has been reported. The Council voted that, in the future, acceptable diathermy machines must be fitted with line filters or other devices to eliminate "feed back" of high frequency current in the power supply lines. The Council plans to enforce this rule in ninety days.

SEAL OF THE COUNCIL

A seal denoting acceptance of a product by the Council has been adopted. The Council also voted that decalcomanias be made available to those who desire to use the seal on apparatus and advertising. Electrotypes of the seal may be obtained from THE JOURNAL.

PUBLICATIONS OF THE COUNCIL

The Council was gratified by the response of the profession now that the original printing of 4,000 copies of the Handbook

is entirely exhausted and that a second printing is necessary. The booklet Apparatus Accepted has been reprinted also. The Council voted that, when it is revised, it be made larger by the addition of general discussion, and that the general appearance be made to conform with that of New and Nonofficial Remedies.

D. C. A. PORTABLE DIATHERMY MACHINE NOT ACCEPTABLE

Manufacturer: Diathermy Company of America, 102 West Forty-Second Street, New York.

The D. C. A. Portable Diathermy Machine is a small unit which is advertised and sold directly to the public by lay salesmen, who are provided with pamphlets and testimonials of lay users. Instruction for its use is given largely by the salesmen.

A copy of the advertising matter, which has been referred to the Council, contains statements such as: "Treat yourself to Health . . . Scientifically—Here is a mild, safe way to get relief from torturing pains without doping yourself with drastic drugs. Diathermy is a scientific method that has been accepted by all leading physicians and hospitals . . ."; "When treating yourself with D. C. A. Diathermy you have no further need for pills, powders, or prescriptions"; "Diathermy not only relieves the pains you already have—it will stop many before they start"; "Diathermy (inner heat) goes deep into the binding congested area—and stays in. People suffering from the following ailments are invited to try diathermy at our expense:—Arthritis, Neuritis, Sciatica, Lumbago, Neuralgia, Pneumonia, Bronchitis, Gout, Asthma, Hay Fever, High blood pressure, Sinus disorders, Poor circulation and many other ailments"; "Only with Diathermy can you expect blessed relief—try it."

One part of the advertisement reads: "No obligation for free home demonstration by trained technician. We have at your disposal a staff of trained technicians who will demonstrate a D. C. A. Diathermy instrument to you in your own home. This visit is without cost or obligation to you. Upon your request by either phone or mail we will be glad to make an appointment to send one of our technicians. D. C. A. Diathermy instruments can be rented for short periods."

The machine appears to weigh about 25 pounds. It is a spark gap machine, equipped with intensity controls and electrodes for application.

In the opinion of the Council on Physical Therapy, the Diathermy Company of America is practicing methods that are detrimental to rational therapeutics. The use of promotional sales methods by those unqualified to practice medicine constitutes an appeal to the public with arguments which are unscientific and may harmfully enhance a feeling of false security on the part of the public.

In view of the foregoing, the Council voted not to include the D. C. A. Diathermy Machine in its list of accepted devices.

AN APPRECIATION

The Council on Physical Therapy wishes to acknowledge, with appreciation, the efforts of the following consultants who have so generously contributed their time to the Council by assisting in the investigation of apparatus and the consideration of other problems that have confronted the Council: Drs. Fred L. Adair, Francis Heed Adler, M. Herbert Barker, William Bierman, Walter Boothby, Joseph Brennemann, Curtis Burnam, Anthony Cippollaro, George M. Coates, L. F. Curtiss, L. W. Dean, Géza de Takáts, F. H. Ewerhardt, Bernard Fantus, Samuel Feinberg, E. P. Fowler, Jonas Friedenwald, Sanford Gifford, F. B. Gordon, Samuel Gordon, Henry Hartig, Austin Hayden, Allan Hemingway, John Severy Hibben, Isaac H. Jones, Kenneth Karl Jones, Frederick T. Kidner, Disraeli Kobak, A. J. Kotkis, Richard Kovács, Henry Laurens, Franklin P. Lowry, Douglas MacFarlan, John MacNie, S. A. Morton, Tell Nelson, Horace Newhart, Robert B. Osgood, Charles Peabody, George Pfahler, John Pribble, Edwin Ryerson, R. Plato Schwartz, B. R. Shurly, Alfred Steegmann, K. W. Stenstrom, Ivan B. Taylor, Clifford B. Walker, Ralph Waters, W. P. Wherry, Miss Gertrude Beard and Mr. S. L. Osborne.

Council on Pharmacy and Chemistry

PRELIMINARY REPORT OF THE COUNCIL

AS A RESULT OF ITS CONSIDERATION OF EVIPAL SOLUBLE, THE COUNCIL VOTED THAT THE DRUG BE DECLARED UNACCEPTABLE UNTIL MORE TRUSTWORTHY METHODS ARE AVAILABLE FOR DETERMINING THE SAFE AND EFFECTIVE DOSAGE UNDER A WIDE VARIETY OF CONDITIONS, UNTIL THE CONTRAINDICATIONS—BOTH RELATIVE AND ABSOLUTE—HAVE BEEN ADEQUATELY DETERMINED, AND UNTIL COMPREHENSIVE PHARMACOLOGIC STUDIES MAKE POSSIBLE THE FIXING OF RESPONSIBILITY OF THE ANESTHETIC IN MANY OF THE AVAILABLE CLINICAL REPORTS OF ACCIDENTS.

ALTHOUGH IT IS NOT THE USUAL CUSTOM OF THE COUNCIL TO SUBMIT TO MANUFACTURERS REPORTS ON PRODUCTS WHICH HAVE NOT BEEN PRESENTED, THE COUNCIL SENT THE WINTHROP CHEMICAL COMPANY, INC., THE REPORT OF ITS CONSIDERATION. THE FIRM REPLIED ON ITS OWN ACCOUNT AND SENT ALSO A REPLY OF DR. WEESE, SOME OF WHOSE WORK WAS DISCUSSED IN THE REPORT. AFTER DUE CONSIDERATION THE COUNCIL HELD THAT NEITHER OF THESE REPLIES OFFERED ANY WARRANT FOR CHANGING ITS DECISION THAT THE PRODUCT IS AT PRESENT UNACCEPTABLE. THE COUNCIL ADOPTED THE FOLLOWING STATEMENT (WHICH IS SUBSTANTIALLY THAT SENT TO THE FIRM) FOR PUBLICATION AS A PRELIMINARY REPORT.

PAUL NICHOLAS LEECH, Secretary.

EVIPAL SOLUBLE

The Winthrop Chemical Company, Inc., has been very active in promoting Evipal Soluble in the United States. It has not, however, presented the product to the Council on Pharmacy and Chemistry. The Council was therefore obliged to take up the consideration on its own initiative.

Evipan (Cyclural), C-C-Cyclohexenyl-N-methyl-barbituric acid, was prepared in the Elberfeld Chemical Laboratory, and in 1932 it was introduced under the name Endorm as a hypnotic having a brief action. Evipan is slightly soluble in water, but the readily soluble salt, Evipan Sodium, was introduced as a general anesthetic to be injected intravenously. The product is still known abroad by the term Evipan, or Evipan Soluble (for the sodium salt). In the United States, Evipal Soluble (Cyclural Soluble) is the market name. Both names (Evipan Sodium and Evipal Soluble) are used in this report, because both are used in the literature; in general, the name Evipal Soluble is used for the product sold in this country and Evipan Sodium for that sold abroad. The ending "al" makes the product consistent with the terminology accepted for most of the hypnotics of the barbituric acid series.

I. PHARMACOLOGY

It would seem almost trite to state that there can be no rational therapeutic use of an agent without adequate knowledge of its pharmacologic actions, but the following discussion of available literature shows that Evipan Sodium was introduced into general use before adequate pharmacologic investigations had been made.

Weese,¹ the director of the pharmacologic laboratories of the I. G. Farbenindustrie A. G. Elberfeld, determined the hypnotic, narcotic and fatal doses of Evipan Sodium for the cat and mouse by oral administration, for the mouse by subcutaneous injection, and for the cat and dog by intravenous injection. He reported that the intravenous narcotic dose for the cat is 25 mg. per kilogram and that the fatal dose is from 100 to 110 mg. per kilogram; that the therapeutic ratio for the cat is 4, while that for the dog is 3.3. He stated that it lacks local irritant actions and side actions as well as after-effects; that the slight affinity for the vital organs explains the slight toxicity and broad therapeutic margin.

Weese² explained later that the action of Evipan Sodium is brief after its intravenous injection because it is destroyed rapidly in the liver, little being excreted in the urine. The narcotic action is prolonged when the function of the liver is impaired. Weese stated that a fatal dose always causes death in the cat by paralysis of respiration. This has been interpreted to apply to man, in which case it is dangerously misleading.

Weese² described six stages of narcosis. That stage which is always induced by the intravenous injection of 25 mg. per kilogram in the cat is termed "rausch." In this stage there is confusion without abolition of the reflexes, but full anesthesia with loss of the reflexes was not always induced with doses

of less than 30 mg. per kilogram. This shows, of course, a lower therapeutic ratio than 4, but the latter fact has been ignored by many who have cited Weese's therapeutic ratio, even when they used full anesthetic doses, with loss of reflexes.

Parsons³ "found that in the cat 0.1 c.cm. of a 10 per cent solution caused a fall in B. P. of 25 mm. Hg. with slow recovery and apnoea for 20 seconds. After a total of 0.6 c.cm. of 10 per cent solution [60 milligrams] artificial respiration was needed and the B. P. fell until death." The rate of the injection is not stated, but these figures suggest a factor of safety, or therapeutic ratio of 2 for full anesthesia [Weese's sixth stage]; they are also in harmony with the results of experiments on guinea-pigs reported by Kennedy, but they are not in harmony with the statement of Weese.

Kennedy⁴ reported a therapeutic index of 4 for mice. There was great variation in the fatal dose, and the therapeutic ratio based on the smallest fatal dose is about 3. Kennedy found guinea-pigs more susceptible than mice, but he does not state the therapeutic factor for these. A dose of 0.4 mg. per 10 Gm. of weight did not produce unconsciousness, and none survived a dose of 1 mg.; hence the indicated therapeutic ratio is evidently less than 2.5. There is no justification for assuming that the therapeutic ratio for man is less than that for the guinea-pig, but these figures have been ignored almost completely by those who used Evipan Sodium for narcosis.

Kennedy observed that sneezing preceded narcosis in mice and that opisthotonos occurred in 25 per cent of the animals before complete muscular relaxation was induced. Many exhibited a fine tremor or violent shaking of the whole body, which was lessened by warming. Death resulted from failure of respiration. Two mice were anesthetized seventeen and eighteen times, respectively, with intervals of one or two days; some liver damage resulted. Kennedy found that toxic properties predominated when frogs were used.

Kennedy and Narayana⁵ found that the frog's heart brought to a standstill by perfusion with solution of Evipan Sodium recovered when perfused with unpoisoned solution. This is in harmony with the results observed by Storm,⁶ who perfused the heart of the monkey. He observed that the slow intravenous injection of 25 mg. per kilogram induced narcosis without excitement in the monkey (*Hylobates* and *Macaca irus*), with abolition of spinal reflexes. Any slight fall of blood pressure resulted from action on the vasomotor centers. Fatal doses caused death by paralysis of respiration before the heart stopped.

Wright⁷ stated that a dose of $\frac{1}{4}$ grain of Evipan Sodium per pound [35.6 mg. per kilogram] caused anesthesia lasting from ten to fifteen minutes in the dog, followed by a narcotic period [attended with incoordination] lasting from three to four hours. He states: "In every case in which it has been used, this period of recovery has been associated with frenzied struggling and excitement, and for this reason we have ceased to use it." Wright is a veterinarian and refers to its use for animals.

Holck and Cannon⁸ reported that delayed death in rats followed apparent recovery from depression induced by Nostal, but not that due to Evipan Sodium or any one of several other barbiturates.

Dallemagne⁹ reported that Evipan Sodium caused serious anemia in dogs, even when the dose was repeated at intervals of several weeks. Clinical reports of the use of repeated doses of the drug do not contain any mention of anemia, even when the dose was repeated twenty-nine times.¹⁰

Schranz¹¹ observed that patients with peritonitis and septic conditions required smaller doses of Evipan Sodium for anesthesia than did the average patient. He found that with the progress of infection and increasing weakness in experimentally infected animals the narcotic dose fell to one-fifth that required

for healthy animals. Velu¹² reported that the injection of a dose of 33 mg. of Evipan Sodium per kilogram caused marked cyanosis in a horse which was severely ill with trypanosomiasis. Von Brandis¹³ found that with increasing depth of narcosis induced by Evipan Sodium or other anesthetic the analeptic effects of epinephrine, caffeine, strychnine, cardiazol, (mitrazol), coramine and strophanthin diminish and finally cease and that in deep narcosis these analeptics injure the circulation and respiration in the rabbit. He states that these results cannot be transferred directly to man. If it is valid to transfer the therapeutic ratio to man, it is difficult to explain why the results observed by von Brandis should not be equally applicable to man.

Fretwurst¹⁴ administered a total of 15 Gm. of Evipan orally to a dog in a period of ten days and recovered 5.6 per cent of the total barbituric acid in the urine, but he did not determine the form in which it was present. He stated that he and Halberkann had found from 1.2 to 4.5 per cent of single intravenous doses in the urine in man.

II. THE THERAPEUTIC USE OF EVIPAN AS A HYPNOTIC

The therapeutic use of Evipan as a hypnotic is of minor importance in the present discussion; hence it will be discussed briefly. Scharpf¹⁵ observed that it induces sleep promptly, and, since its action is brief, he concluded that it is useful for inducing sleep in those who lie awake without pain and for those who awaken early in the morning. He observed no ill effects from its use, with reference to the heart or vascular system, and no effects on the day following its administration. Weese¹ reported that the hypnotic and narcotic doses in animals lie close together, but it is obvious that the hypnotic dose for man when used in this way is far from the full anesthetic dose. Unfortunately the term "hypnotic" is also used to indicate the condition of mental confusion bordering on anesthesia in man. The hypnotic dose in that sense also lies near the narcotic, in fact it is the narcotic, in man.

III. NARCOSIS

The terms basal, basis and induction narcosis and "rausch" are used by different individuals with slightly different meanings, and several have defined these terms. Harms¹⁶ defines "rausch" as the stage between sleep and full narcosis, during which perception of pain is lost but during which the patient is able to answer questions intelligently. It is useful for slight operations, such as simple incisions, and for the removal of teeth. Evipan Soluble has been recommended by many for inducing various stages of anesthesia, and Kamniker and Rintelen¹⁷ stated that it had been generally accepted for "rausch" by those at the German Surgical Congress in 1933.

Baetzner¹⁸ reported that he had used Evipan Sodium in about 400 cases; that his investigation was incomplete, but that he had found it useful for "rausch," preliminary to ether or ethyl chloride, and alone for full anesthesia; that it is harmless and safe, with a complete absence of contraindications; that no special technic or experience regarding dosage is required—one merely follows the rules; that this requires no skill for its administration.

Holtermann¹⁹ used the drug in about 700 obstetric and gynecologic cases and was warm in his praises, recommending it for all short gynecologic operations, but not before delivery in labor, because of want of knowledge of its action on the child. Later Holtermann²⁰ became more conservative after he had used it about 1,800 times, during which he had a fatality. He then maintained that it could not be used with entire safety for full anesthesia.

Kobel²¹ stated that it is increasingly plain that Evipan Sodium is not suitable for long operations. Unfortunately, the conservative view which Kobel expressed so early in the history of the drug was not generally accepted at that time, and Kohlhaage²² maintained that it is useful in suitable cases for

prolonged operations. He opposed its use in obstetrics because of interference with uterine contractions. The difficulty lies in determining which cases are suitable. There is even today a want of agreement, and Coryllos and Bass²³ recommended its use in major operations. Oettle²⁴ probably expresses the opinion of the greater number of conservative observers when he holds that the drug finds its proper field limited to induction and short narcosis.

IV. DOSAGE

Evipan Soluble is sold in ampules each of which contains 1 Gm. of the drug, with an ampule which contains 10 cc. of sterile water. The aqueous solution decomposes in a short time; hence the drug is dissolved in the sterile water just before it is used. It is stated in the advertising and by many authors that this forms a 10 per cent solution and that 1 cc. contains 0.1 Gm. of the drug. The solution prepared according to the printed directions measures slightly more than 10 cc., and 1 cc. contains less than 0.1 Gm. The error is usually negligible, but it should not occur with such a potent drug. The solution made in this way is so generally used that the dosage is almost always expressed in cubic centimeters of this solution, and reference is made to it in the present discussion. Many authors stated in 1933 that they used the doses recommended by the manufacturers. The referee has not seen the earliest advertising of Evipan Sodium, but it is often implied that 10 cc. is the dose recommended. A circular received by a physician in 1935 bears the following statement:

"Simple Dosage Determination

"Estimation of the required dosage is not difficult. It is based essentially on the rapidity and intensity of the effect of the first fraction of the dose on the individual patient. As with other anesthetics, the general condition is also taken into consideration. Furthermore, the maximum of 0.06 cc. of the 10 per cent solution of Evipan Soluble for every pound of body weight is usually not exceeded at a single injection. The adult dose, therefore, ranges from 5 to 10 cc."

The circular contains no instructions regarding the rate of injection, nor does it mention any contraindications specifically. The foregoing statement is in harmony with that of Baetzner, who maintained that one "merely follows the rules," and also with that of Baumecker,²⁵ who stated that initial doses vary from 4 to 5 cc. in about one minute, the remainder more rapidly, the "exact dosage not being given and not necessary." He referred to the dosage recommended by the manufacturers and stated that they recommended a maximum of 10 cc. of the 10 per cent solution. Samuel²⁶ stated that with doses of from 4 to 5 cc. and repetitions of from 2 to 3 cc. one may secure painless childbirth.

Numerous reports of serious accidents and some fatalities following the use of Evipan Sodium soon led to efforts to devise a safe and effective method of administration. This involves two closely related questions. The first is the total dosage; the second is that of the rate of injection.

Baetzner²⁷ stated that it is wrong to follow any schematic dosage; that the hypnotic [light narcotic] dose for some patients is only from 0.5 to 1.0 cc., and that in one case a total of 1.5 cc. sufficed for anesthesia for an operation for hernia in a man of 75; that the elderly and the decrepit seldom require more than 4 cc., and that the use of even that dose often requires extreme care. Simenauer²⁸ reported tolerance [light anesthesia] induced by 0.5 cc. in a man in whom there was closure of the bile duct. Lauber²⁹ reported that sleep followed the injection of only 1 cc. in a man weighing 85 Kg. in whom a total of 3 cc. sufficed for anesthesia during an amputation. Honkamp³⁰ reported that some elderly patients bore doses of 10 cc. well, while some did not. Baetzner³¹ reviewed the subject and stated that much less is needed than was at first supposed; that the chief field is for induction and for short operations. The tone of this paper is in sharp contrast to that of his first.

It was maintained for a time that the drug must be injected fairly rapidly—the total within from two to three minutes—in order to secure a sufficiently high concentration in the blood

stream. Anschuetz³² stated that excitation in the first stage was due to overdosage or to a too slow rate of injection. Laesecke³³ held that injection at a slower rate than 1 cc. in fifteen seconds tends to induce resistance and failure to induce anesthesia.

Smaller doses and a slower rate of injection soon came into use among conservative surgeons, and Gautier³⁴ stated that slow injection is the main consideration and that rapid injection leads to inevitable disaster. He injected pantopon (the hydrochlorides of the alkaloids of opium, principally morphine) and after an hour the solution of Evipan Sodium was injected at the rate of 1 cc. in two minutes. When prolonged anesthesia was desired, Gautier injected from 0.5 to 1.0 cc. every five to ten minutes. There is still some diversity of opinion concerning the optimum rate of injection, but many conservative surgeons inject the solution slowly until twilight sleep is induced, and after an interval of about three minutes, during which the depth of anesthesia increases, additional amounts are injected slowly until the required stage of anesthesia is induced. Prolonged anesthesia is maintained preferably with ether. Some maintain that with the injection of fractional doses of 1 cc. or less the control of anesthesia is equal to that with ether.

The widely different views of equally competent observers may be harmonized in part with the knowledge gained by experience. Rapid injection is not desirable, but it is far less dangerous in young, healthy, strong patients than in elderly, feeble and seriously ill patients, who are peculiarly susceptible to the toxic effects of the drug. Rapid injection is courting disaster with such patients. The question of dosage and the rate of injections are closely connected with those of indications and contraindications, and they cannot be considered wholly independently.

The functional activity of the liver in any patient influences the safety of a given dose of Evipal Soluble, but the anesthetic activity and the toxicity are increased by a great variety of conditions, which must be considered when determining the availability of the anesthetic and in calculating the dosage. Healthy children and strong, healthy, young adults require relatively large doses, and "failures" are more common among such patients than among the elderly. Severe sepsis, ileus, peritonitis, cachexia, emaciation, severe hemorrhage, and anything that tends to lower the resistance of the circulatory and respiratory systems are all indications for the greatest caution with regard to the total dose and to the rate of injection. It is not difficult, therefore, to understand why some patients have been poisoned severely by as little as 2 cc. of the solution, while others have borne total amounts of 50 cc. during prolonged anesthesia, with no obvious injury.

Many use morphine as a routine before general anesthesia without recording the fact, and it is often impossible to know whether it was used in a given case. One is often practically certain that morphine was used in cases in which the effects following the use of very small doses of Evipal Soluble in nearly normal patients greatly exceed those which are to be expected from such doses of the anesthetic alone. Geiger³⁵ reported that he injected 1 cc. of morphine [sic] followed by 25 cc. of Evipan Sodium during an operation lasting three hours on a man of 70 years with excellent results. That suggests either extraordinary good fortune or an extraordinary patient.

The manufacturer does not recommend the use of morphine, but its use permits the utilization of smaller doses of the anesthetic with smoother anesthesia and fewer "failures." The smaller doses of the anesthetic are attended with less frequent tremor and convulsive movements, which often interfere with operation. It is well known that Evipal Soluble and morphine are both depressants of the respiratory center, and there can hardly be a serious question that toxic doses act synergistically to depress the respiration. With wisely selected therapeutic doses of each, the synergistic action on the respiration is often less than that of the total dose of Evipal Soluble which would be required alone to induce the same degree of anesthesia. The Council's referee believes that small doses of morphine—seldom more than 10 mg.—are often desirable; but there is no justifica-

tion for using larger doses of morphine in the form of omnopon or pantopon than would be used in the form of the official morphine sulfate.

One may say that the dose of Evipal Soluble solution varies from 0.5 to 10 cc. for short operations or for induction anesthesia, dependent on many conditions, not all of which can be known in advance. The Council's referee does not believe that larger doses or repetitions of fractional doses should be used for prolonged anesthesia. Stohr³⁶ stated that he had discussed the question of dosage with many surgeons and that it becomes increasingly evident that there is hardly another drug which requires such individualization for safety.

V. ANTIDOTES

Evipal Soluble has the actions of other barbiturates, differing mainly in its rapid decomposition in the liver. Any substance which counteracts the effects of other barbiturates and which acts promptly and without harm to the patient may be useful in treating poisoning with Evipal Soluble; but severe or fatal accidents sometimes follow the injection with such suddenness that little can be done to counteract the toxic effects. One is impressed with the frequency with which observers have reported that they had used lobeline, caffeine, strychnine, coramine, metrazol (cardiazol), epinephrine or oxygen with carbon dioxide and artificial respiration without success. Recent work suggests that picrotoxin may be valuable when we have accurate knowledge of the proper technic for its use under a variety of conditions. It is a very active agent, and capable of causing death when excessive doses are used.

The observation of von Brandis³⁷ that with increasing depth of anesthesia the analeptic action of several of the drugs commonly employed as antidotes to the barbiturates lessens and may even increase the depression in normal animals in deep narcosis helps to explain why these often failed to restore patients who had suffered collapse after the injection of Evipal Soluble.

Lundy³⁷ states that the safe intravenous injection of Evipal Soluble or other barbiturates induces anesthesia so slowly that surgeons complain of the delay; he suggested the addition of 25 mg. of the cardiac and respiratory stimulant pyridine beta-carbonic acid diethylamide to every cubic centimeter of the solution of the barbiturate. This procedure does not impress the referee favorably. Should severe respiratory depression result from overdosage with this method, it would seem to leave no satisfactory resource available.

VI. ADVANTAGES

Some of the advantages of Evipal Soluble can be stated only in general terms, because what constitutes an advantage in one case may be of slight importance in another. A patient's fear and anxiety increase the danger of a severe operation, and the avoidance of psychic disturbance is probably the greatest advantage possessed by Evipal Soluble anesthesia. With the injection of the solution the patient usually experiences nothing more than the prick of the needle before becoming drowsy and losing consciousness almost immediately. When the dose is calculated with skill and the drug is injected slowly in suitable cases, the depth of anesthesia is usually under control nearly equal to that with ether—better, according to a few enthusiasts.

Vomiting occurs less frequently than after ether. It is probable that it occurs after Evipal Soluble alone in about 1 per cent of the cases, but the conflicting testimony is hard to reconcile. Coryllos and Bass,²³ who used preliminary doses of one-third grain of pantopon, reported vomiting in 24.7 per cent of their cases in operations for thoracoplasty. Greenberger and Bass³⁸ reported that 6 per cent of their patients vomited after urologic operations. Several report that none of their patients vomited after the injection of Evipan Sodium alone, and Decker³⁹ stated that none of 112 patients vomited. He used morphine in doses of 20 mg. half an hour before the operation.

Evipal Soluble does not irritate the respiratory passages. This is an especial advantage for patients having bronchial or pulmonary inflammation, and pneumonia occurs less frequently after its use than after ether. Decker also reported that no

case of pneumonia occurred in his series of 112 operations, mainly laparotomies. The anesthetic does not appear to injure the healthy vital organs. The absence of a mask is important in operations about the head.

VII. DISADVANTAGES

Little is said in the advertising about the disadvantages of Evipal Soluble; but many of these are apparent from the present discussion. First in importance, and far outweighing all others, are the uncertainty of the proper dosage in many cases, and the uncertainty regarding the relative contraindications, because so many conditions must be considered and each given its due weight when calculating the dosage.

Evipal Soluble depresses the respiration and the circulation; often sharply, sometimes fatally. Lauber²⁹ states that the fall of blood pressure is greater in patients with arteriosclerosis than in normal persons. It is probable that this explains some of the deaths that have been reported in elderly patients. The fine or coarse tremor (less frequent after morphine), the incomplete relaxation of the abdominal muscles, especially in the presence of reflexes, the necessity of a skilled anesthetist, and the undue prolongation of narcosis even after small doses in some cases are among the disadvantages, some of which have been enumerated previously in this discussion.

Landor and Salleh⁴⁰ reported a case of widespread paralysis which followed the use of Evipal Sodium. There is no evidence that the anesthetic caused the paralysis. Peterkin⁴¹ reported dermatitis in an anesthetist. Belfrage⁴² stated that during the previous year a few cases, three or four he believed, had been described in which Evipal had been followed by severe disturbance of the blood, taking the form of myelogenous leukemia.

VIII. INDICATIONS AND CONTRAINDICATIONS

There is a want of agreement concerning the indications and contraindications for the use of Evipal Soluble. The Anesthetics Committee of the Medical Research Council³ stated that thorough pharmacologic work had been carried out in Germany with Evipal. The individual experiments may have been thorough, but the published results were of limited scope and left much to be learned at the expense of patients. Sauerbruch⁴³ stated that the manufacturers should have made exhaustive studies of the drug before marketing it. This statement was based on the fact that many accidents to patients had occurred. Domanig⁴⁴ expressed agreement with Sauerbruch. Domanig presented an excellent discussion, but much has been learned by clinical experience since his paper appeared.

Evipal Soluble finds its special field of usefulness in the hands of those who are skilled in its use, for light anesthesia or the "rausch" of German anesthetists, which is suitable for short operations, such as simple incisions, changing painful dressings and the removing of teeth; and also for inducing anesthesia which is to be continued with ether or some other volatile anesthetic, provided the patients are in good general condition and are free from disturbance of the circulatory or respiratory system.

One who has had an unfortunate experience with a new anesthetic is inclined to consider certain conditions of the patient in whom the accident occurs as contraindications for that anesthetic. The result is that there are many contraindications reported which do not find general acceptance. Many hold that there is no absolute contraindication but that there are relative contraindications which vary in degree from the almost negligible to nearly absolute. One finds it warmly recommended for conditions that others hold to constitute absolute contraindications.

The consensus of those whose opinions have impressed the Council's referee is that the relative contraindications include liver disease or liver dysfunction, severe septic conditions, ileus, peritonitis, extensive hemorrhage, anemia, emaciation, general weakness, cachexia, phlegmon of the throat, extensive arteriosclerosis, and depressed state of the circulatory or respiratory system. No hard and fast rule can be stated, and skill and experience are required in many cases to determine whether

a given condition, or combination of conditions, constitutes an absolute bar to the use of the drug.

Any relative contraindications must be taken into consideration when calculating the dosage, and with that understanding the drug may be indicated when its advantages outweigh its disadvantages.

IX. SEVERE, BUT NOT FATAL, ACCIDENTS

Weese⁴⁵ stressed the "extraordinary therapeutic ratio of Evipal Sodium, because it has a strikingly slight action on the respiratory and vasomotor center." He had previously stated that there had not been one dangerous occurrence among 10,000 cases of Evipal Sodium narcosis but that there had been one unexplained death. That death was "unexplained" merely because adequate studies of the actions of Evipal Sodium had not been made under widely varying conditions. It was an Evipal Sodium death (reported by Petermann).

Ansuetz³² reported at the German Surgical Congress in April 1933 seven severe accidents that had followed the use of Evipal Sodium. There was severe circulatory failure in five and moderate failure in one. Three of the patients died within thirty-six hours. The Council's referee believes that the drug was partly responsible for one of these deaths and has included it in a list to be given presently.

Stimpfl⁴⁶ collected twelve additional reports of severe accidents involving disturbance of the respiration or circulation or both. He attributed these accidents to overdosage and held that they were avoidable. Toxic actions are evidence of overdosage, but it is precisely because overdosage is so difficult to avoid with surely effective doses that accidents continue to occur.

Ménégaux and Sechehaye⁴⁷ reviewed the literature embracing about 200 papers dealing with Evipal Sodium. They tabulated forty-nine severe accidents, giving the name of the author, the sex, age and weight of the patient, a brief history, the dose (often unknown), the rate of injection, the interval before the onset of the accident, its character, antidotes employed, and the result of the treatment. Five of these patients died, four of them within thirty-six hours; but those authors do not attribute any of these five deaths to the anesthetic. One of the severe accidents occurred after an interval of three days; the referee does not believe that it should have been included in the list, since he does not find any evidence that it was caused by Evipal Sodium.

The onset of the accident was immediate or within five minutes in eighteen cases; in nearly all the others the time of onset is not recorded. In nearly every case there was asphyxia, cyanosis or collapse. Many others have reported severe accidents, and among these Coryllos and Bass²³ as late as 1936. The study of severe accidents throws much light on the cause of death in other cases, and, while the subject is obviously of great importance, a comprehensive discussion of these reports would require more space than can be devoted to it here.

X. DEATHS

Ansuetz³² also reported eight deaths following the use of Evipal Sodium at the same time that he reported the seven severe accidents. These were reported by those who had used Evipal Sodium in 6,460 operations. Several subsequent writers have stated that these eight deaths occurred in the first 6,460 cases in which the drug was used. This is not the case; there had been about 25,000 anesthetics with it apparently, and many reported that there had been no accident.

Ansuetz stated that these deaths were due to relative overdosage but that one reported by Petermann was serious; meaning, presumably, that it was not predictable. Some subsequent writers have concluded that all these eight deaths were due to the anesthetic; others have attributed only one or two of them to the drug.

Stimpfl⁴⁶ listed eleven deaths, including those reported by Ansuetz, one reported by Gritti, one by Killian and one that "occurred in a small hospital."

There was paralysis of respiration in 34 per cent and severe depression or paralysis of the heart or circulation in 38 per

cent of the total of twenty-nine cases—nineteen accidents and ten deaths—with details lacking in the case reported by Gritti. The high percentage of circulatory disturbances is of special importance, because it shows that the statement of Weese that fatal doses always cause death by paralysis of respiration is dangerously misleading. This statement is also made in the literature issued by the manufacturers in such a way as to imply that it is true in clinical cases.

Ménégaux and Secheyaye⁴⁷ tabulated twenty-two deaths that had occurred during or following anesthesia with Evipan Sodium in about 23,000 cases. They state that Jacobson reported another death after the table had been prepared. It is not included in the present discussion because the data do not indicate the cause of death sufficiently. These twenty-two deaths embrace all that Anschuetz had reported and all—with possibly one exception, that reported by "a small hospital"—which Stimpfl listed. These twenty-two deaths are listed here with the numbers used by Ménégaux and Secheyaye, with references to original reports when possible, in order to facilitate the present discussion and for the convenience of the reader in consulting original reports.

It is to be observed that some of the references given here apply to papers published subsequent to that of Ménégaux and Secheyaye.

Ménégaux and Secheyaye eliminate three of these deaths (6, 15 and 9) as certainly due to disease; they state that the cause of death in two cases (8 and 19) is unknown. However, one of these (Nordmann's) is of especial interest because Anschuetz said of this "Do not blame Evipan too much." Nordmann informed Stimpfl that the patient, a man of 86, suffering with gangrene, received a dose of 8 cc. and died from heart failure due to the anesthetic. Four of the deaths (13, 16, 18 and 20) are listed as "probably due to Evipan Sodium" but with serious reservations in three. In five cases (3, 4, 11, 12 and 21) the anesthetic is stated to have been absolutely contraindicated and in nine (1, 2, 5, 6, 7, 10, 12, 14 and 17) it was relatively contraindicated. There was overdosage in eight. They state that it is possible that twelve deaths (3, 5, 6, 7, 10, 11, 12, 13, 14, 17, 18 and 19) were due wholly or partly to Evipan Sodium.

The onset of the accident—not the time of actual death—was "immediate" in seven cases (1, 2, 6, 18, 20, 21 and 22), within one-half to fifteen minutes in six (3, 4, 10, 12, 14 and 17) and "shortly," "at end of operation," or "in some minutes" in three cases (5, 7 and 13).

It would be a remarkable coincidence if there were no immediate connection between cases of overdosage and contraindications and the deaths that followed. There would be no object in mentioning a death under the circumstances if there were no connection between the anesthetic and the cause of death; nevertheless, many of the authors, including Ménégaux and Secheyaye, deny that the deaths which they report were caused by the anesthetic. It is practically certain that some of these deaths would be avoidable in the light of our present knowledge. It is probable that some of these patients would have died with any anesthetic and that some would have died shortly without any anesthetic or operation; but the present analysis

is intended to direct attention to ways of avoiding accidents, not to accuse any individual anesthetist of carelessness.

Stohr and Niederland⁴⁸ tabulated fifteen deaths which they considered as certainly, or almost certainly, due to Evipan Sodium. These include twelve of those reported by Ménégaux and Secheyaye and three reported by Steinbrück. Desplas⁴⁹ attributed twenty-three deaths to Evipan Sodium, with the cause of another in doubt. His list includes three duplications, the record of one which was apparently only a minor accident, not a death, and one of which the referee finds no other record (Bassler's). Two deaths reported by Schmidt and included in the list of Ménégaux and Secheyaye were also reported by Schmutzler.⁵⁰

The referee has collected reports in the literature of twenty-one deaths in addition to the twenty-two reported by Ménégaux and Secheyaye and has analyzed independently the original reports of all but three of the twenty-two included in the list of those authors. The reports of these twenty-one deaths will be reviewed briefly. The dates of the reports are given in the text because it is of interest to consider the list historically. It is certain that some deaths which occurred early in the use of Evipan Sodium were attributed to other causes or to causes unknown, because it was supposed that the anesthetic was free from danger. (Cf. comments on death reported by Petermann). Unfortunately, the date of published reports does not always coincide with the date of the accident.

1. Baucks⁵¹ (1933) reported that a patient with peritonitis, appendicitis and intestinal paralysis collapsed after the injection of 3 cc. of Evipan Sodium; the pulse was imperceptible; the intended operation was not performed; there was slow improvement; death resulted from peritonitis after twenty-four hours. The referee believes that this was a most unfavorable case for the use of Evipan Soluble and that the anesthetic was a contributory cause of death. Baucks also reported that a man of 66 suffered severe collapse after the injection of 2 cc. of Evipan Sodium but recovered; the patient died of intestinal paralysis after an interval of thirty-six hours. It is impossible to state whether the anesthetic hastened the death.

2. Zantop⁵² (1933) reported that the injection of 4 cc. of Evipan Sodium caused sleep lasting three hours in a patient suffering with meningitis. Weakness of the heart and respiration necessitated the use of restoratives; death occurred after an interval of thirty-six hours. The anesthetic probably contributed to the cause of death, which would have occurred shortly had no anesthetic been used.

3. Ducuing and Fabre⁵³ (1934) attributed a death with one of their first eight cases to Evipan Sodium and add "Naturally, we dropped it." The referee accepts their opinion without having had an opportunity to analyze the procedure.

4 and 5. Monod⁵⁴ (1934) reported two deaths following the use of Evipan Sodium. He stated that these deaths were not due to the anesthetic, but Desplas, who heard the report, maintained that the drug caused the deaths. Both patients were poor risks, one with pulmonary abscess complicated by meningitis; the other had cirrhosis of the liver. The referee believes that the anesthetic was at least partly responsible for the immediate deaths but that both patients would have died had it not been given. That may be the basis of Monod's contention that the drug was not to blame. One may be permitted to ask why Monod reported them if the drug was not at least partly responsible for the deaths.

6. Napier and Petrie⁵⁵ (1934) reported that a man in a very toxic state died with cardiac collapse though "usual precautions were taken." The intended operation was not performed, and this was apparently a case in which the anesthetic caused death; but details are lacking.

7-13. Slot and Galley⁵⁶ (1934) reported nine deaths of which they had secured reports. These include one of their own

50. Schmutzler: *Klin. Wchnschr.* **12**: 1309, 1933.

51. Baucks, K.: *Zentralbl. f. Chir.* **60**: 306, 1933.

52. Zantop, H.: *Med. Klin.* **29**: 782, 1933.

53. Ducuing, J., and Fabre, P.-Ch.: *Bull. et mém. Soc. nat. d. chir.* **60**: 1128, 1934.

54. Monod, R.: *Bull. et mém. Soc. nat. d. chir.* **60**: 318, 1934.

55. Napier, R., and Petrie, P. W. R.: *Brit. M. J.* **2**: 534, 1934.

56. Slot, G., and Galley, A. H.: *Brit. M. J.* **2**: 291, 1934.

patients, one reported by Westminster Hospital and five others for "some of which they are indebted to Dr. Morrison." It would appear that this Dr. Morrison was the medical representative of the manufacturers, but such is not stated by the authors. The referee believes that two of the nine deaths may be dismissed as being due to other causes. No. 7 of the present series (the first of these authors) was a patient of the authors. A man of 70 was toxic and suffered from chronic bronchitis, fatty myocarditis, cloudy swelling of the heart and kidney, carcinoma of the tongue, edema and congestion of the lung. He received $\frac{1}{3}$ grain of omnopon and $\frac{1}{150}$ grain of scopolamine followed after an hour by the injection of 8.5 cc. of Evipan Sodium. Comment is superfluous except to state that the patient survived for sixteen hours. It is an astonishing record for the date.

8. (Reported to Slot and Galley by Westminster Hospital.) Death was almost immediate in an extremely unfavorable case after the injection of 3 cc. The necropsy revealed "a piece of tartar as large as a tooth" lodged in the glottis. It was suggested that it caused death. The referee has studied this report and has concluded that the patient probably died of Evipal Soluble, but certainty is impossible.

9. A man of 67 with renal cardiac diseases and bronchitis received an injection of 7 cc. and died under the anesthetic.

10. A woman of 27 received an injection of 10 cc. of Evipan Sodium for an appendectomy and died during the operation. Such a dose is contraindicated in appendicitis, and the referee believes that it caused the death of the patient.

11. A man of 64 had chronic myocarditis, circulatory failure, edema, hydrothorax and a severe toxic oral state; he received an injection of 10 cc. and died "shortly." This is an excessive dose for a man in such a condition, and the cause of death seems obvious.

12. A woman of 50 with advanced cardiac disease and oral sepsis received an injection of Evipan Sodium and died from respiratory and cardiac failure.

13. A woman of 60 with severe rheumatoid arthritis and septic teeth, with extensive myocardial degeneration (shown at necropsy) received an injection of 6 cc. of Evipan Sodium and died at the end of the operation.

14-17. Steinbrück⁵⁷ (1934) reported two deaths and subsequently reported two more. Three of the four are included in the list of fifteen deaths of which reports were collected by Stohr and Niederland. The first of these four (in the referee's list) was that of a woman of 48 whose general condition was poor, in whom there was a diagnosis of phlegmon of the mouth and throat with beginning edema of the glottis. The slow injection of 3 cc. and then of 1 cc. was followed by a sudden change for the worse, cyanosis, superficial respiration, and failure of the pulse. Necropsy revealed also a septic spleen, dilated heart and diseased liver. A less favorable case would be hard to find.

A man of 84 suffering with cancer of the breast received an injection of 7 cc. During a rapid operation, the heart and respiration failed. Restoratives were applied and the patient improved, but he died the next morning. Necropsy showed cancer of the stomach and fatty infiltration of the liver with some pulmonary edema.

A strong, muscular man of 27 suffering with syphilis received an injection of Evipan Sodium for anesthesia for a plastic operation on the palate. There was a pause with the onset of sleep, because of movements, and then a total of 24 cc. (including the first portion) was injected during an operation lasting forty-five minutes. Severe asphyxia was followed in the afternoon by death. Steinbrück states that this dose seemed justifiable on the basis of previous reports. All these four deaths occurred in 1933, but this report was made in 1934.

A man of 70 received an injection of 13 cc. of Evipan Sodium for an operation for hernia lasting thirty-five minutes. Cyanosis developed while the circulation remained good, but all efforts at restoration failed. After these deaths Steinbrück stated that they used Evipan Sodium only for short operations, for which they used from 2 to 4 cc. to induce sleep and followed this with ether. It is obvious that Steinbrück attributes these deaths to the anesthetic.

18. Barnsley⁵⁸ (1934) "was moved by the report of Slot and Galley, and because the mortality from Evipan assumes alarming proportions" to report the following death. A man of 70, suffering from dysphagia, was admitted for esophagoscopy; he was frail and cachectic. After the injection of 5 cc. the pulse became thready at once and finally stopped. Necropsy showed that "the stomach was solid with carcinoma." The anesthetic was the immediate cause of death, though the patient would have died shortly without it.

19. Nordentoft⁵⁹ (1935) reported that a woman of 64 suffering with cardiac dilatation died about three minutes after the injection of 7 cc. of Evipan Sodium, with respiratory and cardiac failure. Carcinoma of the uterus had been suspected, and the woman, almost paralyzed by fear, had insisted that she would die, even though assured that only a minor operation was to be performed. The nervous condition indicated the use of Evipal Soluble, but the patient was an extremely poor risk for other reasons.

20. Kamniker and Rintelen⁶⁰ (1935) reported the death of a man of 70 and that of a woman of the same age. The man died after an interval of three days. The referee does not include this death in the list of twenty-one which is given here. The woman was severely cachectic; she received an injection of 7 cc. of Evipan Sodium, which was followed after five minutes by failure of the heart and respiration. It seems probable that both patients received morphine, though it is not mentioned in the report. It was used in other cases, and its use seems to have constituted a routine procedure.

21. Greenberger and Bass³⁸ (1935) reported three deaths following the use of Evipal Soluble in fifty-two procedures. One patient was severely toxic with perineal abscess and severe infection and had a damaged heart. He received an injection of 10 cc. of Evipal Soluble and died within about four minutes from respiratory and cardiac failure. The dose was excessive under the circumstances, and the cause of death seems obvious. Muscular movement induced by the anesthetic contributed to injury of the bladder in one case and thereby probably contributed indirectly to the cause of death in one of the three patients. The third death was apparently due to other causes and does not require further consideration here.

It is obvious that, so long as reports are made without the name of the surgeon or anesthetist in charge, one cannot be absolutely certain that one has avoided duplication in every case. The referee has tried to avoid such duplication, and, on the other hand, he may have omitted some deaths, such as that "reported by a small hospital."

SUMMARY AND CONCLUSIONS

Evipal Soluble (Evipan Sodium) was introduced as a general anesthetic to be injected intravenously before adequate studies had been made of it under a great variety of conditions.

Evipal Soluble probably has a narrow field of usefulness in which it may be employed with relative safety provided it is used with skill and with due regard for its limitations. The contraindications—both relative and absolute—are numerous, but they have not been determined with sufficient precision to permit of the use of the substance with absolute safety in many conditions.

Reports of severe and fatal accidents have been discussed. The referee has examined the readily available data concerning a number of deaths which have followed the use of Evipal Soluble (Evipan Sodium). It is believed that the anesthetic is wholly or partly responsible for forty-three deaths listed in this report, though several of these deaths would have occurred shortly with any anesthetic, and in the absence of any.

It is probable that the preliminary use of morphine contributed to the cause of death in some of these cases. The failure of some operators to report the use of morphine increases the difficulty of analysis of the cause of death. While morphine may have contributed to the cause of death in some cases, as stated, it is equally possible that it lessened the danger in others.

SATURDAY, APRIL 3, 1937

SPRAY RESIDUE ON FOODS

In order to minimize the possibility of poisoning from foods contaminated by lead or other metallic spray residues, the federal government has established maximum values for the amounts of these metals that may be present in sprayed fruits intended for interstate commerce. The Council on Foods of the American Medical Association has voted that no food shall use the seal of acceptance if it contains more than two parts of lead per million of food. Tolerances for arsenic and copper also have been adopted. Laws to protect consumers of fruits and vegetables distributed in intrastate commerce exist in only two states, Colorado and Michigan. A recent report¹ emphasizes the urgent need for state laws of this type. Analyses were made on various lots of apples of different varieties intended for local distribution in Iowa, a state without spray residue regulations. Lead was determined by the diphenylthiocarbazone procedure as an index to the amount of spray residue present. Although most of the samples contained amounts of lead within the 1935 federal tolerance of 0.018 grain per pound (equivalent to 2.5 parts per million) five lots showed larger amounts, ranging from 0.024 to 0.027 grain per pound.

Studies were also made to detect possible toxic effects of the sprayed apples. Both normal human subjects, who ate two apples daily from fall until early spring, and guinea-pigs fed apples from the same source were used. Blood smears were made at regular intervals and treated with a modified Mason's methylene blue stain, a stain said to give the most consistent results in the detection of the effects of lead as revealed by the blood picture.² The smears from both the human subjects and the guinea-pigs gave no indication of increased amounts of basophilic materials over that present in normal controls, thus indicating that the small amounts of lead ingested under the conditions of the experiment exerted no detectable toxic effects. One case was

reported, however, of a person who ate three apples from a sprayed orchard and developed symptoms of arsenic poisoning shortly thereafter. The apples, he noted, were coated with a whitish substance, which he partially removed with a handkerchief. A severe diarrhea developed on the following day and continued for a second day. Subsequently a marked anal itching developed, followed by an urticarial type of dermatitis, which spread rapidly over the entire buttocks. Twenty-four days after the patient had eaten the apples, and shortly after he was admitted to a hospital, an itching maculopapular rash appeared in the lumbar region and soon spread over the entire trunk and extremities. The rash disappeared in a few days and the patient made an uneventful recovery. Arsenic was found in the patient's urine following admission to the hospital and the case was diagnosed as arsenic poisoning from the spray residue on the apples.

Even though no definite evidence of toxicity was observed in the subjects who ate sprayed apples as described, the fact that one case of arsenic poisoning from sprayed fruit was observed and the lead content of some lots of apples exceeded the federal tolerance warrant the author's recommendation that applegrowing states should enact laws to protect consumers against spray residues on fruits and vegetables. The use of the 1 per cent hydrochloric acid rinse procedure outlined by the United States Department of Agriculture³ is suggested as a simple and reliable procedure, which would at least mitigate a potential danger.

SYPHILIS IN THE MAGAZINES

The tabu against discussions of syphilis in newspapers and popular magazines is no more. A few diehards among the editors continue to avoid the subject, but general recognition of its importance is spreading rapidly. Much credit attaches therefore to the *Chicago Tribune*, which apparently saw the trend of public thought in time to open up the subject before other newspapers or magazines ventured the chance of public disapproval by seriously discussing this problem.

In the March and April issues of the *Reader's Digest* (edited by DeWitt Wallace and Lila Bell Acheson) articles have been published by Drs. John H. Stokes and Thomas Parran which are models for this type of discussion going to the public. There is no exploitation of the writer; there is excellent presentation of the subject; there is proper consideration of the public health and private practice aspects of the subject. Surgeon General Parran points out that free drugs and reliable laboratory service made available to private physicians would permit many marginal patients able to pay only small amounts for treatment to be served by a personal physician instead of being shifted to the impersonal public clinic. In a recent address he empha-

1. Heeren, R. H., and Funk, H. B.: Toxicity of Fruit Sprays, Pub. Health Rep. 52:8 (Jan.) 1937.
2. McCord, C. P.; Holden, F. R., and Johnston, Jan.: Basophilic Aggregation Test in the Lead Poisoning Epidemic of 1934-35, Am. J. Pub. Health 25:1089 (Oct.) 1935.

3. Farmer's Bulletin 1752, U. S. Department of Agriculture, August 1935.

sized also the danger of having public demand for medical service created beyond the ability of either the medical profession or the public to supply that service.

Another periodical that has contributed notably in recent articles to the proper exploitation and advancement of medical service is the *Redbook* (under the editorship of Edwin Balmer). An earlier article by Morris Markey, a reporter of considerable repute, revealed to the public the questions at issue with relationship to the problem of state medicine. In the April issue of the *Redbook* he discusses the present status of the syphilis problem. Mr. Markey provides not only a brief history of the advancement of our knowledge of this disease but also explicit directions for the public as to what to do when confronted with the possibility of a case in the reader's own family. It is doubtful whether any better advice has been given by anybody than appears in the following concluding three paragraphs of his article:

The rule becomes simple. Take every possible precaution against infection. If you think you might have been exposed to infection, through a kiss or any other contact, take the easy precaution of soap and water. If any symptoms at all appear, don't groan in secret and horrified misery. Get to a doctor. The blood test is a simple and painless affair, requiring about two minutes of your time. It will tell you whether to go on home and forget your anxieties, or whether to tell your doctor that the quicker he begins his treatments, the quicker you will be over with the thing—perfectly normal again, healthy, able to marry and have children with no fear of the consequences.

The blood test is not expensive. You can get one for a dollar or two, or you can get it free by going to a clinic, if you can't possibly afford to pay your doctor. You can get treatment free, too, if you can't afford to pay your doctor.

If you do not know a doctor, or how to find the clinic, call up your county medical association—the number will be in the phone book—or call up your local public health director. Whatever you do, place yourself immediately in the hands of a medical man. Do, literally, everything he tells you to do, for it is by his help, and his alone, that you will get well—and that you will avoid passing the disease on to some other poor victim.

In the *American Mercury* there is a flippant but at the same time somewhat perspicacious article by Anthony M. Turano pointing out many of the inconsistencies in our attitudes on this subject. It is very easy to be sarcastic now but it is doubtful that much is to be gained by pummeling a dead body. The prudery in regard to syphilis has just about vanished and the great danger now, as said in *THE JOURNAL* some weeks ago, is overemphasis. Certainly it would be too much to hope that all state legislatures would immediately pass adequate laws in relationship to the control of venereal diseases. Legislatures seem either to be twenty years ahead of what medicine can prove or twenty years behind what it already has proved.

Attention should also be called to the manner in which *Time*, *News Week*, *Literary Digest* and *Collier's* have considered this subject. Apparently our editors have merely been waiting for the opportunity to join in this campaign and now that the ground has been broken, we may expect a reasonable amount of discussion in all periodicals devoted to current interests.

CONTRACEPTIVE ADVICE, DEVICES AND PREPARATIONS STILL CONTRABAND

The United States circuit court of appeals for the second circuit, Dec. 7, 1936, affirmed a decree of the United States district court for the southern district of New York dismissing an action brought by the United States for the forfeiture of a package offered for importation, containing certain articles to prevent conception; namely, 120 pessaries more or less.¹ These pessaries, it appears, were sent by a physician in Japan to a physician in the United States, for trial in her practice and an expression of her opinion as to their usefulness for contraceptive purposes. The tariff act of 1930,² which prohibits the importation of articles for the prevention of conception, makes no exception in favor of physicians or in favor of the importation of contraceptive articles for the prevention or cure of disease. The government, therefore, instituted proceedings to have the pessaries offered for importation forfeited. Defeated in the trial court, it appealed to the United States circuit court of appeals for the second circuit, a circuit covering only three states, Connecticut, New York and Vermont. "The question is," said the appellate court, "whether physicians who import such articles as those involved in the present case in order to use them for the health of their patients are excepted by implication from the literal terms of the statute." After quoting the law of the state of New York, which permits the furnishing of articles for the prevention of conception to physicians who may in good faith prescribe their use for the cure or prevention of disease, the circuit court of appeals held that the tariff act of 1930 forbidding the importation of articles for the prevention of conception did not bar the importation of articles employed by physicians in their professional practice for the purpose of saving life or promoting the well being of their patients.

The circuit court of appeals seems to have based its decision in part on the assumption that the tariff act of 1930, so far as it relates to the importation of articles for the prevention of conception, embraces only such articles as Congress would have denounced as immoral if it had understood all the conditions under which they were to be used. In the opinion of the court, the purpose of the act "was not to prevent the importation, sale, or carriage by mail of things which might intelligently be employed by conscientious and competent physicians for the purpose of saving life or promoting the well being of their patients." One of the three justices of the court, however, although concurring in its judgment, said "There seems to me substantial reason for saying that contraceptives were meant to be forbidden, whether or not prescribed by physicians, and that no lawful use of them was contemplated."

1. *United States v. One Package*, 86 Fed. (2d) 737.
2. 18 U. S. C. A., sec. 396.

The decision of the court obviously relates only to the matter before it; namely, the right of physicians to import contraceptive articles "for the purpose of saving life or promoting the well being of their patients." It rests largely on the assumption by the court as to what Congress would or would not have done if it had understood certain conditions, and on the assumption that Congress did not understand such conditions. Whether other United States circuit courts of appeal throughout the United States, of equal rank, and the United States Supreme Court, if the issue comes before it, will indulge in such assumptions, it is impossible to foresee. The present decision has no reference to the right of physicians to advise the practice of conception, or to operate on or treat a patient to accomplish that end, or to prescribe or supply articles for the prevention of conception. Federal law, in fact, except in the territories and the District of Columbia and in other places under the exclusive jurisdiction of the federal government, is powerless with respect to such matters, except as they involve the use of the United States mails or enter into interstate or foreign commerce. With those exceptions, the law of the state is supreme within its own territorial jurisdiction.

Now the National Committee on Federal Legislation for Birth Control, Inc., has sent out printed copies of the decision in the present case, under glaring headlines, "NOW BIRTH CONTROL IS LEGAL." It has sent to the secretaries of county medical societies throughout the United States letters proclaiming the decision "as a bill of rights for the medical profession" and requesting that the members of the societies be notified that "NOW contraception may take its rightful place in preventive medicine and public health" and that "physicians may NOW give contraceptive advice in public as well as private practice; that hospitals, dispensaries and public health agencies may—and should—NOW include birth control in their services." The committee, too, has suggested to editors that they bring to the attention of their readers information concerning the alleged establishment of "the legality of medical practice in the field of contraception." This propaganda is essentially misleading. The decision on which it is based means merely that physicians who desire to import pessaries for contraceptive purposes from Japan or other countries, through Connecticut, New York and Vermont, within the second judicial circuit of the United States, may do so.

Physicians who desire to import contraceptive devices and preparations through ports elsewhere than in New York, Connecticut and Vermont cannot rely altogether for protection on the decision of the circuit court of appeals for the second circuit; outside its own circuit its decision is not binding but is only of persuasive influence. In the District of Columbia and in the territories, the laws of the United States still forbid the giving of information or the distribution of devices and appliances for the prevention of conception and

make no exception in favor of physicians. The decision on which the National Committee on Federal Legislation for Birth Control has relied to support its propaganda has and can have nothing to do with the legality or illegality of the practice of contraception within any state except as that practice may involve foreign and interstate commerce or the use of the mails.

COOPERATIVE MEDICINE

In the organization section in this issue of *THE JOURNAL* appears a discussion of cooperatives. Dr. James Peter Warbasse, president of the Cooperative League of the United States, has set forth his ideas of how cooperation may be applied to the provision of medical service, in a pamphlet published by the league under the title "Cooperative Medicine." It is difficult for him or for any one else to reconcile cooperative principles with any proposal to furnish medical service. He concludes that, since medical colleges and hospitals had low standards when they were owned and operated by physicians, consumer control would improve these standards; the medical profession, however, raised the standards, not any lay organizations or the government.

Dr. Warbasse suggests that the "cooperative method" requires a "group of 150 to 500 families, who should unite to employ a physician full time." Then he throws away the cooperative principle of equality and accepts the professional principle of the sliding scale in the conclusion that "it is best that the annual costs per member be graded according to family income." He would have three income classes, one of which would pay \$40, one \$20 and one \$10 a year. Just how would this differ from the sort of contract medicine that has been built up by lodges and other groups, and still more frequently by unscrupulous promoters?

While he insists that "only high class physicians would be brought into the project," nowhere does he tell how this can be done in view of the opposition of physicians, which is based on the fact, learned from hard experience, that such methods lead to deterioration of service and attract only the incompetent and unethical physician. He warns groups to "beware lest a physician who is not well qualified for the position take the initiative in organization for the purpose of making a job for himself." This is exactly what has happened and what would continue to happen.

Dr. Warbasse is himself too thoroughly familiar with the conditions of good medical practice to suggest that one of the fundamental principles of cooperation should be put into operation; namely, buying at wholesale, selling at the market price, and distributing the difference as a "patronage dividend." He also realizes that the selection of a physician for others by the directors of the scheme would not please everybody. As to those who are not pleased, he says "There remains only one thing for them to do: that is, to withdraw from the

organization." Dr. Warbasse's essay leads to just one logical conclusion: A man who is both a sincere cooperator and a competent physician finds his intellect in a civil war; it is impossible to reconcile these two positions sufficiently to apply cooperative principles in practice to medical service.

Current Comment

POISON GAS

The threat of the use of poison gas in strife among European nations now casts its shadow over all the world. The British Medical Association has issued instructions to all physicians and pharmacists for the use of gas masks and the treatment of gas injuries. In most European countries physicians and pharmacists are the agents disseminating the information for combating gas attacks. Some governments have instituted drills in the use of gas masks by the people generally and have built gas proof cellars as places of refuge during attacks. America cannot overlook this potential menace which has accompanied the advances made by science. As poison gases are manufactured and used in industry as well as in civil strife, knowledge of the antidote and safeguards against injury should be made available. With an ever greater use of chemicals by the average citizen, there is an increasing toll of casualties arising from poison gases. Death will often result if the attendant cannot recognize the nature of the poison to which the victim has been exposed. Without special training a physician could not efficiently treat cases involving the newer organic poisons. Many agencies will be required to develop and collect accurate information on this subject and to disseminate the information in sufficient detail to make it usable to the physician, to his co-workers in the hospitals and pharmacies, and to the public at large. Such information is important in industry and in war.

EFFECT OF GARLIC ON THE FLAVOR AND ODOR OF MILK

In spite of several recent studies of the question, the source of garlic breath odor remains a somewhat controversial subject. Babcock,¹ in a United States Department of Agriculture bulletin, in 1925 reported a group of studies on cows which may throw some further light on this matter. The defined objectives mentioned in that report were to determine how garlic flavor and odor entered milk, to determine the length of time required after consumption of garlic for the flavor and odor to enter the milk, and to determine the length of time after cows consumed garlic before the flavor and odor disappeared from the milk. The garlic fed to the nine Jersey and seven Holstein cows used in the observations was of the variety commonly found growing wild. Only the garlic tops were fed and at the time of feeding were about ten or twelve inches high. Samples were taken from the milk of

each cow at the time of milking, given a key number and cooled but not aerated. The samples were judged for flavor and odor by experienced judges who had no knowledge of the key. When samples of milk were taken between three and one-half and five minutes after feeding the garlic, only 12.5 and 6.3 per cent of the opinions rated the milk normal in flavor and odor, respectively. The brevity of this interval indicated that it was not necessary for garlic to be taken into the stomach of the cow before entering the blood stream and thence passing to the udder. In another group of experiments the cows were forced to inhale garlic odor for ten minutes and were then milked at varying intervals after inhalation. When the cows were milked two minutes after inhaling garlic for ten minutes the garlic flavor and odor were pronounced in the milk. The odor was even more pronounced than the flavor. To determine whether garlic could be detected in the blood, cows were fed two pounds of garlic tops, and blood samples were taken from the jugular vein sixteen minutes, thirty minutes and forty-five minutes after feeding. The sample drawn sixteen minutes after feeding was rated "not perceptible," as the judges failed to identify a garlic odor. In the two later samples the garlic odor was readily identified. A comparison of these blood tests with the milk tests showed what appears to be a discrepancy in time. This may be due to one or more causes. Thus, the garlic flavor and odor may have an affinity for fat and therefore pass rapidly from the blood to the milk. It may also be that garlic is more easily preserved in milk than in blood. The principal deductions, however, are obvious.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSAS

Dr. Vinsonhaler Is Still Dean.—Dr. Frank Vinsonhaler writes that he has not retired as dean of the University of Arkansas School of Medicine, Little Rock, and that the date of his retirement has not been determined.

Officers of State Health Board.—Dr. Fergus O. Mahony, El Dorado, was elected president of the state board of health at its quarterly meeting, Little Rock, February 18, succeeding Dr. William G. Hodges, Malvern. Dr. Melvin E. McCaskill, Little Rock, was chosen vice president.

Society News.—Dr. T. Duel Brown, Little Rock, among other speakers, discussed renal abnormalities before the Tri-County Clinical Society in Hope, February 25.—Dr. Fred H. Albee, New York, addressed the Pulaski County Medical Society at the University of Arkansas School of Medicine, Little Rock, February 15, on the value of electrically driven tools in bone surgery.

CALIFORNIA

Hospital Meeting.—The eleventh annual convention of the Association of Western Hospitals, Association of California Hospitals, western conferences of the Catholic Hospital Association and allied groups and sections will be held April 12-15 at the Biltmore Hotel, Los Angeles. According to the preliminary program, the following topics will be discussed: manifold obligations of the hospitals to the public; legislation and hospitals; group hospitalization; the interest of the patient is paramount; the growth, causes and cures of malpractice suits; employee welfare in the broader sense.

1. Babcock, C. J.: Effect of Garlic on the Flavor and Odor of Milk, Bull. 1326, U. S. Department of Agriculture, March 18, 1925.

Lectures on Speech Defects.—Dr. Paul Moses, lecturer in speech defects, University of California Medical School, San Francisco, opened a series of lectures at University Hospital, February 24, with a talk entitled "The Significance of Phonetics in Medical Practice; Selected Topics from the Neurology of the Voice." He spoke, March 3, on "The Relationship Between Voice, Constitution and Character," and, March 10, "Pathology and Therapy of Speech and Voice Diseases." Dr. Moses concluded the series, March 17, with a lecture on "Functions, Diseases and Therapy of the Singing Voice."

Charter Week Celebration.—Clinics, lectures and the annual dinner of the University of California Medical School Alumni Association made up the program for the medical school's observance of "charter week," March 24. The lecturers included:

Ernest L. Walker, Sc.D., Treatment of Malignant Tumors.
Dr. Howard C. Naffziger, Back Pain.
Dr. Fred H. Kruse, Peptic Ulcer.
Hermann Sommer, Ph.D., Shellfish Poisoning.

The departments of medicine, pediatrics, obstetrics and gynecology, pathology and bacteriology cooperated in a symposium on syphilis in the morning, and the annual dinner was addressed by Monroe E. Deutsch, LL.D., vice president and provost of the university, and Dr. Herbert C. Moffitt, clinical professor of medicine.

DELAWARE

Review Course on Obstetrics.—The Delaware Academy of Medicine, Wilmington, instituted a review course on obstetrics, March 11, to continue for six weeks. Dr. Philip F. Williams, assistant professor of obstetrics, University of Pennsylvania School of Medicine, Philadelphia, gave the first lecture on "Causes of Maternal Deaths—Based on Study of Philadelphia Deaths." Dr. Carl H. Davis, Wilmington, is completing the series. The state board of health and the New Castle County Medical Society are cooperating.

FLORIDA

State Medical Meeting at St. Petersburg, April 5-7.—The sixty-fourth annual meeting of the Florida Medical Association will be held at the Vinoy Park Hotel, St. Petersburg, April 5-7, under the presidency of Dr. Orion O. Feaster, St. Petersburg. Papers will be presented by the following:

Dr. Jewel G. Gailey, Blountstown, Some Observations on Blood Pressure.
Dr. Theodore F. Hahn Jr., De Land, Trichinosis.
Dr. William C. Blake, Tampa, Diagnosis of Coronary Heart Disease.
Dr. Turner Z. Cason, Jacksonville, Heart Block.
Dr. Joseph S. Stewart, Miami, Treatment of Tetanus.
Dr. Henry E. Palmer, Tallahassee, Syphilis.
Dr. Douglas D. Martin, Tampa, Acute Appendicitis in Children.
Dr. Wilbur A. McPhaul, Jacksonville, Cooperation of State Board of Health and Medical Profession.
Dr. Wiley M. Sams, Miami, Use and Abuse of the X-Rays in the Treatment of Skin Diseases.
Dr. Cayetano Panettiere, Miami Beach, Carcinoma of the Body of the Uterus.
Drs. Arthur H. Weiland and Charles R. Burbacher, Coral Gables, Gonorrheal Arthritis.
Dr. Lloyd J. Netto, West Palm Beach, Traumatic Surgery.
Dr. Harry Bernard McEuen, Jacksonville, Reaction Following Application of X-Ray Therapy.
Dr. Charles B. Mabry, Jacksonville, A Simplified Method of Treating Fractures of the Shaft of the Humerus.
Dr. Hermon Marshall Taylor, Jacksonville, Deafness from Drugs.
Dr. Joseph Ralph Vallotton, Daytona Beach, Recent Advances in the Diagnosis and Treatment of Asthma.
Dr. Gerard Raap, Miami, Use of X-Radiation in Conditions Other Than Malignancy.
Dr. Robert B. McIver, Jacksonville, Surgery of the Ureter.
Dr. Henry Mason Smith, Tampa, Hypoglycemic Shock Therapy in Schizophrenia with Report of Cases.

Dr. Morris Fishbein, Editor of THE JOURNAL, will address a public meeting in Williams Park Monday evening on "Food Fads and Follies." Dr. John H. J. Upham, Columbus, Ohio, President-Elect of the American Medical Association, will appear on the program. Other organizations meeting at the same time include the woman's auxiliary, the Florida Railway Surgeons' Association, Florida Radiological Society, Florida Society of Dermatology and Syphilology and the Florida Pediatric Society.

ILLINOIS

Refresher Courses on Obstetrics and Pediatrics.—A series of lectures on obstetrics and pediatrics is being offered throughout the state as a part of the national program to improve conditions for mothers and children in rural areas. The project is under the direction of a specially appointed committee on infant and maternal welfare in cooperation with the state department of public health, the state medical society, the Illinois Academy of Pediatrics and the American Committee on Maternal Welfare. Dr. Harold H. Hill, formerly associate in the department of obstetrics and gynecology,

University of Illinois College of Medicine, Chicago, as field consultant, is in charge of arrangements. The series opened March 4 in Lincoln with a program for the DeWitt and Logan county medical societies. Dr. Louis Rudolph discussed the management of obstetric hemorrhage and Dr. Clifford G. Grulee, Evanston, infant feeding and prophylaxis of contagious disease. In Sangamon County the program opened March 11 at Springfield and in McLean County March 18 at Bloomington. Each series will run for six weeks consecutively.

CHICAGO

Hospital News.—Presbyterian Hospital expended \$846,571.52 in 1936 to care for 11,503 patients in the hospital and 31,879 nonhospital patient visits. An additional \$96,129.53 was expended to maintain the school of nursing and nurses' home, while the cost of free care given to 5,554 part pay and 2,437 free patients was \$183,299.50.

Meeting on Conservation of Health.—The Chicago Medical Society held a public meeting on conservation of health, March 17, with Dr. Burt R. Shurly, Detroit, as the guest speaker. Dr. Shurly discussed the periodic health examination, and the following Chicago physicians spoke on special subjects: Drs. Austin A. Hayden, hearing; Nathan S. Davis III, heart; G. Henry Mundt, vision, and Arthur H. Conley, orthopedics.

Personal.—Mr. Harry N. Gottlieb has been elected president of the Michael Reese Hospital.—Dr. Arno B. Luckhardt, professor of physiology, School of Medicine, Division of the Biological Sciences, University of Chicago, has been elected a fellow in the International Society of Anesthesia Research in recognition of his discovery of ethylene as an anesthetic.—Dr. Livingston Farrand, who will retire as president of Cornell University, Ithaca, N. Y., June 30, was guest of honor at a banquet, March 12, given by 500 alumni of Cornell from the Chicago district.

Society News.—Drs. Walter Freeman and James W. Watts, Washington, D. C., addressed the Chicago Neurological Society, February 18, among others, on "Subcortical Prefrontal Lobotomy in the Treatment of Certain Psychoses."—The German Medical Society of Chicago was addressed, March 2, by Drs. Adalbert Klaptoz on "Dwarfism Resulting from Hypophyseal Tumor: Operation per Nasal Route," and Otto Meyer, New York, "The Clinical Syndrome of Latent Phlebitis."—At a meeting of the Chicago Society of X-Ray Technicians, March 4, Drs. Ralph G. Willy and Edson W. Carr discussed "The Use of Pitressin as an Aid in X-Ray Diagnosis" and "Darkroom Troubles" respectively. Dr. Marie Ortmyer demonstrated the gastroscope.

INDIANA

Society News.—Dr. Morris Edward Davis, Chicago, among others, addressed the Tippecanoe County Medical Society, Lafayette, March 9, on "Treatment of Hemorrhage Late in Pregnancy."—Dr. Charles P. Emerson, Indianapolis, discussed "The Emotional Element in the Etiology, Course and Prognosis of Disease" before the Indianapolis Medical Society, March 23.

IOWA

Personal.—Drs. Harley L. Sayler and Fred L. Wells, Des Moines, have been granted life membership in the Iowa State Medical Society.—Dr. Azel Ames Jr., formerly of Cincinnati, has been appointed assistant professor of surgery in the State University of Iowa College of Medicine, Iowa City.—Dr. Norman W. Phillips, Clear Lake, was guest of honor at a reception, March 5, in celebration of his completion of fifty years in the practice of medicine.

Speakers' Bureau Activities.—The speakers' bureau of the state medical society recently sponsored a series of lectures on medicine for relief workers, at the request of the director of medical relief of the Iowa Emergency Relief Administration. The bureau is also presenting weekly lectures at Drake University, Des Moines, for which students will be allowed one hour's credit. A series of lectures is also being arranged for the students of Upper Iowa University at Fayette.

Tuberculosis, Heart and Sanatorium Associations Meeting.—The Iowa Tuberculosis Association, the Iowa Sanatorium Association and the Iowa Heart Association held a joint meeting in Des Moines, March 11-12, with headquarters at the Hotel Savery. The first day was devoted to symposiums on prophylaxis and early diagnosis of heart disease, essentials of diagnosis of pulmonary tuberculosis, collapse therapy in pulmonary tuberculosis and coronary thrombosis, and the tuberculosis problem today was considered from various perspectives in a combined medical and lay program Friday.

KANSAS

New Health Officers.—The following physicians have been appointed county health officers:

Dr. William K. Fast, Atchison, Atchison County.
Dr. Fred L. Holcomb, Coldwater, Comanche County.
Dr. William S. Gooch, Fort Scott, Bourbon County.
Dr. Lawrence F. Schuhmacher Jr., Meade, Meade County.
Dr. William L. Wilmoth, Blue Rapids, Marshall County.
Dr. Merle L. Whitney, Virgil, Greenwood County.

Spring Assembly.—The annual spring clinical assembly of the Sedgwick County Medical Society will convene in the Allis Hotel, Wichita, April 6. Clinics will be held by members of the society and the rotating staff of the Sedgwick County Medical Society. Guest speakers include Drs. Edward W. Alton Ochsner, professor of surgery, Tulane University of Louisiana School of Medicine, New Orleans, and Henry M. Winans, professor of medicine, Baylor University School of Medicine, Dallas.

KENTUCKY

Personal.—Dr. Benjamin T. Black, Campbellsville, for more than eleven years coroner of Taylor County, recently observed the completion of fifty years in the practice of medicine.

Society News.—Dr. Marvin P. Rucker, Richmond, Va., addressed the Jefferson County Medical Society, Louisville, March 1, on "The Effect of Diet on Pregnancy," as guest of the Louisville Obstetrical and Gynecological Society. Flood activities were described by Drs. Hugh R. Leavell, health officer of the city, John D. Trawick, of the county, and Arthur T. McCormack, of the state.—Dr. Robert Julian Estill, Lexington, addressed the Bourbon County Medical Society, Paris, February 18, on "Pneumonia in Children."—Dr. Elmer S. Maxwell, Lexington, addressed the Scott County Medical Society, Georgetown, February 25, on nephritis.

MARYLAND

Dean of School of Hygiene and Public Health.—Lowell J. Reed, Ph.D., since 1925 professor of biostatistics at Johns Hopkins University, Baltimore, has been appointed dean of the School of Hygiene and Public Health, succeeding Dr. Allen W. Freeman, who has been identified with the school since 1921 and dean since 1934. Dr. Reed will take the post July 1. A graduate of the University of Maine, Dr. Reed took the degree of doctor of philosophy at the University of Pennsylvania in 1915. He alternated on the faculties of both universities until 1917, when he became director of the bureau of tabulation and statistics of the War Trade Board, Washington, D. C. In 1918 he became associate professor of biostatistics at Johns Hopkins and professor in 1925. Dr. Freeman served as state health commissioner of Ohio before joining the Johns Hopkins School of Hygiene and Public Health in 1921. Prior to that he had been demonstrator in physiology of the Medical College of Virginia, 1906-1907, medical inspector of the Richmond Health Department, 1907-1908; assistant commissioner of health of Virginia, 1908-1915; state director of the Rockefeller Hookworm Commission for Virginia, 1910-1914, and epidemiologist of the U. S. Public Health Service, 1915-1917.

MICHIGAN

Graduate Courses.—The department of postgraduate medicine of the University of Michigan Medical School, in conjunction with the Wayne University College of Medicine and the Michigan State Medical Society, announces the following short courses:

April 5-10, electrocardiographic diagnosis.
April 12-16, diseases of metabolism.
April 26-May 1, ophthalmology and otolaryngology.
April 8-May 27, diseases of the blood and blood-forming organs.
April 1-May 20, surgery.
June 28-August 6, medical roentgenology (advanced).
June 28-August 20, laboratory technic; clinical microscopy.
June 28-August 20, summer session courses.
April 19-21, pediatrics.
April 26-28, proctology.
April 29-May 1, diseases of the genito-urinary tract.
May 3-7, gynecology, obstetrics and gynecologic pathology.
May 10-14, general medicine.

Sessions will be held at University Hospital, Ann Arbor, and Herman Kiefer, Receiving, Henry Ford and Children's hospitals, Detroit. Additional information may be obtained from the director of the department of postgraduate medicine, University of Michigan, Ann Arbor.

Personal.—Dr. John McLean, Hartford, observed his ninety-seventh birthday recently.—Dr. Charles A. Cooper, Trimountain, has been appointed chief of the medical staff of the Quincy Mining Company.—Dr. Alden G. Sheets has been elected mayor of Eaton Rapids, which has a population of 2,822.—Dr. Joseph L. Egle has been appointed medical director of the

Gaylord Tuberculosis Sanatorium, Gaylord.—Dr. Clarence E. Humphrey, medical secretary of the Wayne County Medical Society, Detroit, has been selected as president-elect to succeed the late Dr. Frederick B. Burke. He will serve until the annual meeting of the society in May.—Elizabeth C. Crosby, Ph.D., professor of anatomy, University of Michigan Medical School, Ann Arbor, was guest of honor at a dinner, February 2, given by former students whose researches were supervised jointly by the late Dr. Gotthelf Carl Huber and Dr. Crosby. The dinner commemorated the recent publication of the Huber Memorial Volume and was a tribute to Dr. Crosby's help in the preparation of the investigations reported therein, according to the *University Hospital Bulletin*.—Dr. Norbert A. Wilhelm, Boston, was elected superintendent of Butterworth Hospital, Grand Rapids, effective April 1.

MINNESOTA

Graduate Medical Institutes.—The Center for Continuation Study at the University of Minnesota will offer three institutes for practicing physicians during April. Provided the enrolment is sufficient, a course on roentgenologic diagnosis will be held April 12-17, one on irradiation therapy April 19-21, and a third on physical therapy April 22-24.

Dr. Evans Is Guest Lecturer.—Dr. Herbert M. Evans, professor of anatomy and Morris Herzstein professor of biology, University of California Medical School, Berkeley, will address the Minnesota Pathological Society, April 20, on vitamins. He will discuss the same subject the following evening under the Clarence Martin Jackson Lectureship. The lectureship is sponsored by the Phi Beta Pi medical fraternity.

Society News.—Dr. Felix R. Nager, professor of otolaryngology, University of Zurich, discussed "Pathology of Petrositis" before the Minnesota Academy of Ophthalmology and Otolaryngology, February 9, in Minneapolis, and Dr. Cecil S. O'Brien, professor of ophthalmology and head of the department, State University of Iowa College of Medicine, Iowa City, "Tuberculosis of the Anterior Uvea."—Dr. Henry E. Sigerist, Baltimore, discussed "The Social History of Medicine" before the Hennepin County Medical Society, Minneapolis, March 1. Dr. Edwin O. Strassmann, Berlin, Germany, discussed "State Medicine in Europe" before the society, February 3.—Dr. Siegfried J. Thannhauser, Boston, delivered a Mayo Foundation lecture at Rochester, February 8, on "Chemical, Physiologic and Clinical Aspects of Cholesterol."

MISSOURI

Officers of Health Board.—Dr. Edward S. Smith, Kirksville, was elected president of the state board of health, January 30, succeeding Dr. Timothy S. Bourke, Kansas City. Dr. Walter L. Brandon, Poplar Bluff, was chosen vice president, succeeding Dr. William T. Elam, St. Joseph.

Society News.—At a joint meeting of the St. Louis Medical Society and the midwestern and southern sections of the American Congress of Physical Therapy, St. Louis, March 9, Drs. Géza de Takáts, Chicago, discussed "Management of Peripheral Vascular Disease"; Frank H. Krusen, Rochester, Minn., "Physical Therapy in Fibrositis," and Disraeli W. Kobak, Chicago, "Clinical Limitations of Short Wave Diathermy."

Speed Factor in Motor Vehicle Accidents.—A survey was recently made in St. Louis to determine whether speed is a dominant factor in motor vehicle accidents, according to *Illinois Health News*. A maximum speed limit of 30 miles an hour was set and facilities arranged for strict enforcement for thirty days. During the thirty days there were three deaths caused by motor vehicle accidents against fourteen during the thirty days immediately preceding and an average of thirteen per month during 1935. Compared with the thirty days immediately preceding the experimental period, the motor vehicle accidents of all kinds declined by 17.1 per cent, injuries involved in motor car accidents dropped 22.1 per cent, fatalities 77 per cent, hospital cases 20.2 per cent, skull fractures 71.4 per cent, hit and run cases 62 per cent. According to the report, excessive speed is a dominating factor in these accidents and must be controlled to insure safety on the streets.

NEW JERSEY

Personal.—Dr. Berthold S. Pollak, who has completed thirty years as medical director of the Hudson County Tuberculosis Hospital, Secaucus, was honored by a reception at the hospital January 31. Dr. Pollak is to be medical director of a new tuberculosis hospital in the Jersey City Medical Center, now nearing completion.

Handbook of Procedures in Preventive Medicine.—The *Journal of the Medical Society of New Jersey* published as a supplement to its March issue a handbook of procedures in

preventive medicine. Twelve chapters bear the headings: the family doctor, organization, fundamental principles, maternal welfare, child health, crippled children, tuberculosis, cancer control, venereal disease control, mental hygiene, health examination of adults and communicable diseases. It has sixty-eight pages and is bound in heavy paper.

NEW MEXICO

Two Years of Public Health Work.—The New Mexico Bureau of Public Health has published its biennial report covering the year 1935 and the first ten months of 1936. A system of health districts was put into effect July 1, 1935, and in February 1936 social security funds became available. These two events have brought about rapid development. A division of epidemiology was added to the health bureau in 1936, making possible an enlarged program for control of communicable diseases. Typhoid is one of New Mexico's most serious problems because of poor sanitation in much of the state and lack of understanding by a large part of the population of the manner in which the disease is spread. In 1935, 435 cases of typhoid were reported and in the ten months of 1936, 321 cases. More than 12,000 persons were immunized in the fiscal year 1935-1936. Diphtheria has declined in the past four years; 673 cases were reported in 1932, 231 in 1935 and 152 in 1936. Scarlet fever was the most prevalent of all communicable diseases. The bureau has supplied antisyphilitic drugs free, and five free clinics for diagnosis and treatment have been established by local health departments. There were 1,191 cases reported during the period of the report compared with 369 in 1932, an increase attributed to better reporting. Tuberculosis is one of the most important problems. The influx of cases from other states creates a hazard to the native population and many cases of local origin are not seen by a physician. Until 1935 tuberculosis was the principal cause of death and in 1935 it tied for second place with pneumonia; heart disease was first. The general death rate was 13.7 per thousand of population. Under the federal works program a new building for the state laboratory at the University of New Mexico at Albuquerque is under construction. During the period of the report the laboratory has examined 76,219 specimens for diagnosis of such diseases as undulant fever, typhoid and bacillary dysentery in addition to routine work. A special study of dysentery is under way in cooperation with the U. S. Public Health Service. Funds supplied by the Public Health Service, the Children's Bureau and the Commonwealth Fund of New York have promoted the development of the public health nursing program. In 1930 the state had sixteen public health nurses and in 1936 it had fifty-eight, forty-two in county health work, ten employed by school boards and six in supervisory positions.

NEW YORK

Personal.—Dr. William C. Treder, Scotia, has been appointed health officer of Schenectady County. He is a former president and secretary of the Schenectady County Medical Society and has been county coroner since 1921.—Dr. Henry D. Watson, Binghamton, was honored at a testimonial dinner January 12 given by the Broome County Medical Society, which he had served as secretary for twenty-seven years.—Dr. Arthur W. Elting, Albany, has resigned as chairman of the attending staff of Albany Hospital, after ten years' service. Dr. William P. Howard succeeded him.—Dr. George H. Whipple, Rochester, will deliver the fourth annual Alexander Van Rensselaer Lecture at the Drexel Institute of Technology, Philadelphia, April 15. His subject will be "Blood Hemoglobin Production Within the Body as Influenced by Diet and Other Factors Under Experimental Conditions."

New York City

The Sir Robert Jones Lecture.—Dr. Albert H. Freiberg, professor of orthopedic surgery, University of Cincinnati College of Medicine, delivered the seventh Sir Robert Jones Lecture at the Hospital for Joint Diseases, February 18. His subject was "Orthopedic Surgery in the Light of Its Evolution."

Symposium on Neoplasms of the Lung.—The Tuberculosis Sanatorium Conference of Metropolitan New York will hold its tenth clinical session on chronic pulmonary diseases at Cornell University Medical College, April 7. A symposium on primary neoplasms of the lung will be presented by Drs. Wolfgang Grethmann, Coleman B. Rabin, William F. Riehoff Jr., Baltimore, and Milton Sills Lloyd.

Friday Afternoon Lectures.—Dr. Reginald Fitz, Boston, delivered one of the series of Friday afternoon lectures of the Medical Society of the County of Kings, March 19, on

"Treatment of the Diabetic at Home." Other speakers in the series are Drs. Charles F. Geschickter, Baltimore, on "Breast Tumors"; Percy S. Pelouze, Philadelphia, "Blood and Pus in the Urine," and Lee M. Hurd, New York, "Diagnosis and Treatment of Nose and Throat Diseases."

Dr. McGoldrick Honored.—Dr. Thomas A. McGoldrick, chief surgeon of St. Peter's Hospital, was the guest of honor at a dinner arranged by the hospital staff, February 8, at The Towers. Dr. McGoldrick is president of the Medical Society of the County of Kings and chief surgeon of the police department. He was graduated from Long Island College Hospital, now Long Island College of Medicine, in 1896 and was for a number of years a member of the faculty. Among the speakers at the dinner were Drs. Charles Gordon Heyd, President of the American Medical Association; Charles H. Goodrich, president-elect of the Medical Society of the State of New York; John E. Jennings and Thomas M. Brennan. About 500 persons attended the dinner.

Society News.—At a joint meeting of the New York Neurological Society and the section of neurology and psychiatry of the New York Academy of Medicine, March 2, the speakers were Drs. Samuel W. Hamilton, on "The Organic Syndrome in the Psychoses"; Nolan D. C. Lewis, "Constitutional Factors in the Paranoid Psychoses," and William H. Dunn, "An Evaluation of the Biochemical Approach to the Psychoses."—Dr. Elliott P. Joslin, Boston, addressed the Medical Society of the County of Queens, February 23, on "Treatment of Diabetes with Protamine Insulin," and Dr. Beverly C. Smith, on "Treatment of Surgical Complications in Diabetes."—Dr. Abernethy Benson Cannon was the speaker at a stated meeting of the New York Academy of Medicine, March 3, on "Significance of Serologic Tests in Syphilis."

NORTH CAROLINA

New Health Officers.—Dr. Murray P. Whichard, Edenton, has been appointed health officer of Chowan County. Dr. Robert M. Bardin, Rutherfordton, recently health officer of Rutherford County, has been appointed in Richmond County to succeed Dr. Bennie B. Dalton, Rockingham; Dr. Charles H. Peete, Warrenton, in Warren County, and Dr. John S. Anderson, New Bern, in Craven County. Dr. Marion H. Seawell, Jackson, has resigned in Northampton County.

OHIO

New Officers of State Medical Board.—Dr. Lee Humphrey, Malta, was elected president of the State Medical Board of Ohio at a recent meeting; Dr. Floyd S. Meck, Cleveland, was elected vice president, Dr. Chester W. Waggoner, Toledo, treasurer, and Dr. Herbert M. Platter, Columbus, was reelected secretary. Other members of the board are Drs. John H. J. Upham, Columbus, President-Elect of the American Medical Association; John R. Shoemaker, Cuyahoga Falls; Roy C. Hunter, Wapakoneta, and Louis T. Franklin, Chillicothe.

Society News.—Dr. Owen H. Wangenstein, Minneapolis, addressed the Academy of Medicine of Cleveland, March 19, on "Management of Intestinal Obstruction." Members of the Cincinnati Academy of Medicine presented the program of the academy, February 19, as follows: Drs. Marion A. Blankenhorn, "A Clinical Study of Pellagra in Birmingham, Ala."; Lee Foshay, "Tularemia," and Howard D. McIntyre, "Problems of Infectious Polyneuritis."—Dr. George F. Cahill, New York, addressed the Summit County Medical Society, Akron, March 2, on "Hirsutism and Virilism, with Adrenal Studies." Dr. William B. Castle, Boston, addressed the society, February 2, on "The Treatment of Anemia from the Point of View of the General Practitioner."—Dr. Alfred A. Jenkins was elected president of the Cleveland Medical Library Association at its annual meeting January 15, and Dr. Harry D. Piercy, secretary. The library has endowments of more than \$300,000 and a collection of 51,000 volumes.

PENNSYLVANIA

Personal.—The board of managers and the staff of Reading Hospital gave a dinner February 10 in honor of Dr. John Lincoln Bower, Birdsboro, who has been a member of the staff for thirteen years. Dr. William S. Bertolet, Reading, was toastmaster.—Dr. John L. Atlee Sr. has been appointed medical director of St. Joseph's Hospital, Lancaster, to succeed Dr. Newton E. Bitzer, who has been made medical director emeritus.—Dr. Joseph Scattergood, West Chester, was honored at a dinner given by the Chester County Medical Society, February 24, in recognition of his twenty-nine years of service as secretary of the society. Dr. John A. Farrell was toastmaster. Dr. Joseph Scattergood Jr. has succeeded his father as secretary.

Society News.—Dr. John Huber Wagner, Pittsburgh, addressed the Cambria County Medical Society, Johnstown, March 11, on "Fractures in General Practice."—Dr. Thomas A. Shallow, Philadelphia, addressed the Luzerne County Medical Society, Wilkes-Barre, in February, on "Diagnosis of Upper Abdominal Surgical Pathology."—Dr. W. Norman Elton, Reading, was elected president and Dr. Abner H. Bauscher, Reading, president-elect of the Northeastern Pennsylvania Chapter of the National Society for the Advancement of Gastro-Enterology at its organization meeting at Easton February 3. Dr. Frederick G. Robinson, Scranton, was made vice president and Dr. Gilbert I. Winston, Reading, secretary.—Drs. William Devitt and Ross K. Childerhose, Allenwood, addressed the Lycoming County Medical Society, Williamsport, March 12, on "Early Diagnosis and Treatment of Pulmonary Tuberculosis in Its Early Stages."—Dr. Arthur M. Dannenberg, Philadelphia, addressed the Lebanon County Medical Society, Lebanon, March 9, on "Childhood Tuberculosis."

Philadelphia

Executive Secretary Appointed.—Mr. Harry J. Rodgers has been appointed executive secretary of the Philadelphia County Medical Society to succeed the late Franklin M. Crispin. Mr. Rodgers has been a member of the staff of the city department of health for more than twenty years, according to the *Weekly Roster and Medical Digest*.

Graduate Seminars.—A group of seminars on physical diagnosis has been presented recently under the auspices of the Philadelphia County Medical Society, as follows:

February 12, Dr. William D. Stroud, Determination of Cardiovascular Efficiency.

February 19, Dr. James Alexander Clarke Jr., The Nontuberculous Chest.

February 26, Dr. John A. McGlinn, Gynecologic Findings and Interpretations in Routine Examinations.

March 5, Dr. Charles W. Dunn, Obscure Endocrinopathies.

Public School for Crippled Children.—The J. Willis and Elizabeth Martin Orthopedic School was opened February 5 to care for all crippled children in Philadelphia. Special equipment includes a swimming pool, specially designed baths and showers, orthopedic desks and chairs. Classrooms are large, with desks widely spaced and ample room for wheel chairs. An infirmary, shops for handicraft work, a sun room and a gymnasium are other features. Busses will bring the children to the school. The building cost \$600,000, part of which was supplied from WPA funds.

Society News.—The section of otolaryngology of the New York Academy of Medicine held a joint meeting with the section on otolaryngology of the College of Physicians of Philadelphia, March 17, with the following speakers: Drs. Horace J. Williams, on "Acute Leukemic Labyrinthine Disease"; Walter Hughson, "Significance of Experimental Otology," and Gabriel Tucker, "Bronchoscopy in the Management of Postoperative Pulmonary Complications."—At a meeting of the Philadelphia Neurological Society, March 19, the speakers included Drs. Eleanor Scott on "The Possible Cerebral Factor in Hypertension" and Robert A. Matthews, "Chronic Encephalitis: Symptomatic Treatment with Benzedrine Sulfate."

Pittsburgh

Personal.—Dr. Waid E. Carson has been appointed professor of ophthalmology in the University of Pittsburgh School of Medicine.

Society News.—At a meeting of the Allegheny County Medical Society, March 16, the speakers were Drs. William W. McFarland, on the work of the general health council; Chauncey L. Palmer, pending health legislation, and George R. Harris, provisions of the compulsory health insurance bill.—Dr. Alfred Stengel, Philadelphia, delivered the Drs. Charles and Karl Emmerling Memorial Medical Lecture of the Pittsburgh Academy of Medicine, March 23. His subject was "The Influence of Abdominal Diseases on the Heart and Circulation."

SOUTH CAROLINA

State Medical Meeting at Columbia.—The eighty-ninth annual session of the South Carolina Medical Association will be held in Columbia, April 13-15, at the Jefferson Hotel. The guest speakers will be Drs. Morris Fishbein, Chicago, Editor of THE JOURNAL, who will address a public health meeting Wednesday evening, April 14, on "Food Fads and Follies," and Abernethy Benson Cannon, New York, who will speak at a luncheon meeting on "Skin Problems Encountered in General Practice." Dr. Fishbein will also speak at the laying of the cornerstone of a new building of the South Carolina Tuberculosis Sanatorium, State Park, sponsored by the Grand

Lodge of Masons of South Carolina in the afternoon of April 14; his subject will be "Weapons Against Tuberculosis." Dr. Cannon will conduct a skin clinic Thursday morning April 15. Among South Carolina physicians on the program will be:

Dr. Douglas Jennings, Bennettsville, Ectopic Pregnancy.

Dr. Charles O. Bates, Greenville, Psychoneurosis Following Injury.

Dr. Walter R. Mead, Florence, Recognition, Differentiation and Management of the Commoner Cardiac Crises.

Dr. Leon Banov, Charleston, The Medical Profession and the Public Health.

Dr. Julian P. Price, Florence, Pernicious Malaria in Children.

Drs. Francis B. Johnson and James E. L. Reveley, Charleston, Meningococcal Meningitis—An Analysis of 100 Cases.

During the meeting a new psychopathic building will be dedicated at the South Carolina State Hospital, with Dr. Walter L. Treadway, head of the division of mental hygiene of the U. S. Public Health Service, Washington, D. C., as the guest speaker. Dr. Robert C. Bruce, Greenville, is president of the association.

SOUTH DAKOTA

Meningitis in Custer.—Newspapers reported March 20 that six deaths had occurred in an epidemic of meningitis at Custer. The outbreak started in a Civilian Conservation Corps camp; four of the victims were members of the corps and two were citizens of Custer.

TENNESSEE

State Medical Meeting at Knoxville.—The one hundred and fourth annual meeting of the Tennessee State Medical Association will be held in Knoxville, April 13-15, under the presidency of Dr. Wilson L. Williamson, Memphis. The guest speakers will be Drs. Charles Gordon Heyd, New York, President of the American Medical Association; Norman L. Higinbotham, New York; Louis A. Buie, Rochester, Minn., and Frank E. Whitacre, Chicago, now conducting graduate courses in obstetrics in the state. Among Tennessee physicians listed on the tentative program are:

Dr. Robert B. Wood, Knoxville, The Commoner Clinical Allergies.

Dr. Philip H. Levinson, Chattanooga, Angina Pectoris and Coronary Occlusion: Diagnosis and Treatment.

Dr. Barney Brooks, Nashville, Results Obtained in About 300 Operations in the Past Ten Years in Vanderbilt Hospital on Patients More Than 70 Years of Age.

Drs. William D. Haggard and James Kirtley Jr., Nashville, Ligation of Saphenofemoral Junction with Retrograde Sclerosing Injections for Varicose Veins.

Drs. Nicholas Gotten and Otis S. Warr, Memphis, Relation of Water Balance to Intracranial Pressure.

Dr. Jere L. Crook, Jackson, Radium—An Indispensable Means of Therapy in Its Field of Service to Humanity.

Dr. William Battle Malone, Memphis, Gas Gangrene—Its Prevention and Treatment.

Meeting with the association will be the Tennessee Academy of Ophthalmology and Otolaryngology, April 12, and the Tennessee Pediatric Society, April 13. Among speakers before the academy will be Drs. Marvin M. Cullom, Nashville, on "Chronic Purulent Otitis Media and Mastoiditis," and Charles K. Lewis, Memphis, "Injection of the Sphenopalatine Ganglion for the Relief of Facial Neuralgia." Guest speakers at the pediatric meeting will be Drs. Alfred A. Walker, Birmingham, Ala., on "Enlargements of the Spleen in Infants and Children"; Laurence R. DeBuys, New Orleans, "The New-Born," and Joseph Yampolsky, Atlanta, Ga., "A Comparative Study of the Use of Acetarsone and Other Drugs in the Treatment of Syphilis in Children."

TEXAS

Changes in State Health Department.—Dr. William Arthur Smith, San Antonio, has been appointed director of mental hygiene in the state department of health, and Dr. Robert B. Wolford, formerly of Wichita Falls, director of the bureau of communicable diseases. Dr. Smith was formerly assistant superintendent of the San Antonio State Hospital, having resigned to enter private practice.

WASHINGTON

Society News.—Dr. Winchell McK. Craig, Rochester, Minn., addressed a special meeting of the Spokane County Medical Society, Spokane, March 29, on "Surgical Treatment of Hypertension." Dr. Eugene B. Potter, Seattle, addressed the society, March 11, on "Surgical Treatment of Peptic Ulcer."—Dr. Karl A. Menninger, Topeka, Kan., addressed the King County Medical Society, March 15, on "The Psychoneurotic and the General Practitioner."

Fifty Years of Practice.—Dr. Orville R. Allen, Lake Stevens, was honored by the Snohomish County Medical Society with a complimentary dinner February 11 at the Monte Cristo Hotel, Everett, in celebration of his fiftieth year of practice.

Dr. Allen was born in Illinois, where his father was a partner of Abraham Lincoln in a grist mill, according to *Northwest Medicine*. He graduated from Rush Medical College, Chicago, in 1887 and practiced in Missouri and in several towns in Washington before settling in Lake Stevens in 1914. An oil painting of Dr. Allen by Mrs. Allen was presented to the medical society to hang in its library.

WISCONSIN

University News.—Dr. Phillips F. Greene, chief surgeon of Yale-in-China Medical School and Hospital, Changsa, Province of Hunan, China, gave an address at the University of Wisconsin Medical School convocation, March 11, on medical opportunities in the Orient. Dr. Greene is spending this year at Yale University and New Haven Hospital. —Dr. John H. J. Upham, Columbus, Ohio, President-Elect of the American Medical Association, gave an address at Marquette University School of Medicine, Milwaukee, February 20, on "Changing Times in Medicine."

PHILIPPINE ISLANDS

New Dean of Medical School.—Dr. Antonio G. Sison, professor of medicine, College of Medicine, University of the Philippines, Manila, has been appointed dean of the college to succeed Dr. Fernando Calderon, who retired in October 1936. Dr. Sison is 53 years old and graduated from University of Pennsylvania School of Medicine, Philadelphia, in 1908. He is a former chairman of the medical division of the Medical Research Council of the Philippines and has been president of the Manila Medical Society and the Philippine Islands Medical Association.

PUERTO RICO

Course for Tuberculosis Workers.—An institute for tuberculosis workers was conducted at the University of Puerto Rico, March 10-18, under the personal direction of Philip P. Jacobs, director of publications and extension, National Tuberculosis Association, New York. The course was designed for the social workers and nurses under the direction of the department of health, although other persons were admitted. It was adapted to the needs and problems in Puerto Rico.

GENERAL

American Leprosy Foundation.—The board of directors of the Leonard Wood Memorial for the Eradication of Leprosy has approved the use of the name American Leprosy Foundation to identify its activities in this country and abroad. The board felt that the change was necessary since the activities of the organization had taken on an international character and because the name Leonard Wood Memorial means little outside the United States. It emphasizes that while the new name has been approved the corporate name has not been changed.

Opportunity for Physicians in California.—The California State Personnel Board is holding an examination May 1 for the position "physician and clinical pathologist." The examination is open to physicians in all parts of the United States who are graduates of approved medical schools with three years of experience in the licensed practice of medicine with specialization in clinical pathology, bacteriology and serology or some other equivalent combination of education and experience. The applicant must have a license to practice in California or be able to secure one. Age limits are from 26 to 50 years. Applications should be filed with the California State Personnel Board, Sacramento, Calif., before April 24.

Association for Study of Neoplastic Diseases.—The annual meeting of the American Association for the Study of Neoplastic Diseases will be held in Philadelphia at Jeanes Hospital April 8-10. Among those who will participate in the discussions will be:

Dr. George A. Stewart, Baltimore, Cured Cases of Cancer.
Dr. Elwood E. Downs, Woodbury, N. J., Effects of Radiation on the Lungs in the Treatment of Breast Cancer.
Dr. Albert DeCrombrughe, Washington, D. C., Eye Tumors.
Dr. Edward B. Soper, Philadelphia, Lymph Nodes.
Dr. Charles F. Goss, Philadelphia, Tumors of the Ovary.
Dr. Stanley P. Lippman, Philadelphia, Chemical Factors Concerned in Cell Growth and Development.

Dr. Stewart is president of the association and Dr. Eugene R. Whitmore, Washington, D. C., secretary.

Progress in Use of Standard Nomenclature.—The National Conference on Nomenclature of Disease states in its annual report that nearly 300 hospitals are now using the standard nomenclature sponsored by the conference. The conference conducts a large correspondence with physicians and hospitals concerning the nature of disease, and the nomenclature has become a textbook in diagnosis and only secondarily

a list of diseases, the report says. Financial assistance is afforded by the Commonwealth Fund, the Metropolitan Life Insurance Company, the Carnegie Corporation and the fifty-four member hospitals of the conference. Dr. Haven Emerson, New York, is president of the conference, Dr. Henry A. Christian, Boston, vice president, and E. H. Lewinski-Corwin, Ph.D., secretary.

Grants Available from Plotz Foundation.—Applications for grants of funds for research in medicine and surgery from the Ella Sachs Plotz Foundation must be in the hands of the executive committee before May 1. As a rule preference is given to research on a single problem or on closely allied problems, but during the present great need for funds grants will be given in the sciences closely related to medicine without reference to special fields. The maximum size of the grants will usually be less than \$500. There are no formal application blanks, but letters asking for aid must state definitely the qualifications of the investigator, an accurate description of the proposed research, the size of the grant requested and the specific use of the money. It is desirable to include letters of recommendation from the directors of the laboratories or clinics in which the work is to be done. Applications should be sent to Dr. Joseph C. Aub, Collis P. Huntington Memorial Hospital, 695 Huntington Avenue, Boston. During the past year thirty grants were made by the foundation, eighteen of which went to scientists outside the United States. In the thirteen years of its existence the foundation has made 282 grants.

Lectures on Growth and Development of the Child.—The concluding lectures in the radio forum on the growth and development of the child, under the auspices of the National Congress of Parents and Teachers, the American Academy of Pediatrics and the National Broadcasting Company, are as follows:

Charles W. Savage, professor emeritus of physical education, Oberlin College, Oberlin, Ohio, April 7, Physical Education for Growing Children.

Dr. Joseph Brennemann, chief of staff, Children's Memorial Hospital, Chicago, April 14, Disease and the Doctor's Side of Growth.

Dr. Martha M. Eliot, assistant chief, Children's Bureau, U. S. Department of Labor, Washington, D. C., April 21, Effects of Family Income on a Child's Growth.

Dr. Richard A. Bolt, director, Cleveland Child Health Association, April 28, Effect of Child Labor on Growth.

Dr. Carroll E. Palmer, medical officer in charge of child hygiene investigations, U. S. Public Health Service, Washington, D. C., May 5, Growth of Children During Wars and Depressions.

Louis I. Dublin, Ph.D., statistician, Metropolitan Life Insurance Company, New York, May 12, Health Hazards in the Period of Growth.

Dr. Henry E. Sigerist, William H. Welch professor of the history of medicine, Johns Hopkins University School of Medicine, Baltimore, May 19, Old and New Thoughts About Growth.

The lectures are on the Blue network of the National Broadcasting Company every Wednesday from 4 to 4:30 p. m., eastern standard time.

Society News.—The Alpha Mu Pi Omega Fraternity will hold a luncheon and biennial meeting at 12 noon at the Hotel Madison, Atlantic City, June 9.—The Western Branch of the American Public Health Association will hold its eighth annual meeting in Phoenix, Ariz., April 13-15.—Dr. Donald B. Armstrong, New York, has been reelected president of the National Health Council and Maurice A. Bigelow, Sc.D., New York, secretary. The American Red Cross and the Maternity Center Association have become active members.—The Tri-State Hospital Assembly of Illinois, Indiana and Wisconsin will be held May 5-7 at the Hotel Sherman, Chicago.—Dr. Herman L. Kretschmer, Chicago, was elected president of the Clinical Society of Genito-Urinary Surgeons at its recent annual meeting in Chicago. Dr. John R. Caulk, St. Louis, was chosen vice president, and Dr. Henry G. Bugbee, New York, was reelected secretary. The next annual meeting will be held in Boston.—At the annual meeting of the American Orthopsychiatric Association in New York, February 19-20, Dr. George J. Mohr, Chicago, was elected president and Dr. Norvelle C. La Mar, New York, secretary. The next meeting will be in Chicago, Feb. 24-26, 1938.—The luncheon of the Phi Rho Sigma medical fraternity during the annual session of the American Medical Association in Atlantic City will be at the Hotel Ambassador, Wednesday, June 9.—The Catholic Hospital Association of the United States and Canada will hold its annual meeting at the Stevens Hotel, Chicago, June 14-18.—Clarence C. Little, Sc.D., Bar Harbor, Maine, was reelected president of the American Birth Control League at its annual meeting in New York in January.—Dr. J. Frank Highsmith, Fayetteville, N. C., was chosen president-elect of the Tri-State Medical Association of the Carolinas and Virginia and Dr. Howard R. Masters, Richmond, was elected president at the annual meeting in Norfolk, February 22-23. This is the first time the association has elected a president-elect. Elected as vice presidents were Drs. David C.

Wilson, Charlottesville, for Virginia; David W. Ruffin, Ahoskie, for North Carolina, and Charles N. Wyatt, Greenville, for South Carolina. Dr. James M. Northington, Charlotte, N. C., was made secretary. Next year's meeting will be in Asheville. Guest speakers were Drs. Frank H. Lahey and Elliott P. Joslin, Boston.

Pathologic Specimens in Otolaryngology Available for Loan.—The division of otolaryngology of the Registry of Pathology in Otolaryngology, Army Medical Museum, Washington, D. C., has assembled a loan collection of histopathologic preparations. Twenty-five sets are available. Requests should be sent to the curator of the Army Medical Museum, with a check for \$25 as a deposit. On the return of the set after three weeks, the money will be returned, minus the cost of shipment. If a preparation is broken or lost during the loan there will be a charge of \$1 per preparation. An album of microphotographs of the preparations and photographs of the gross specimens, together with descriptive material, will be furnished with the loan set. Fifty-one specimens have been assembled during the two years existence of the division of otolaryngology of the registry and it is hoped that the number may be raised to 100 preparations. To this end, specimens should be sent to the museum in the proper containers and solution together with a fairly complete history of the cases from which they are taken. Diagnosis will be made and a section will be sent to any one that sends a gross preparation. It is to be understood that there is no time limit for the return of the preparation because the laboratory of the division is not competing with any other laboratory. The Army Medical Museum, under the direction of the surgeon general of the U. S. Army, has had a registry for a number of years in the branches of ophthalmology, dental surgery, bladder tumors and lymphatic tumors. The division in otolaryngology was established two years ago through the efforts of Dr. Joseph C. Beck, Chicago, who is its director, and under the auspices of the American Academy of Ophthalmology and Oto-Laryngology. Any member of the academy or any otolaryngologist sponsored by a member of the academy can obtain the loan of these sets. Any further information may be obtained from the curator of the museum.

FOREIGN

International Ophthalmological Congress.—The fifteenth International Ophthalmological Congress will be held in Cairo, Egypt, December 8-14. The official subjects to be discussed are "Arterial Hypertension of the Retina" and "Endocrinology and the Eye." The secretary general of the congress is Dr. M. Tewfik, P. O. B. No. 2001, Cairo, Egypt.

St. Thomas's Hospital Begins New Series of Reports.—St. Thomas's Hospital, London, has issued the first volume of a new series of reports which is a departure from its former style. The hospital began to publish reports in 1835, but this effort did not continue beyond 1836. Continuous publication was begun in 1870. With the development of general periodical medical literature, contributions of original articles waned until latterly the report has consisted principally of statistics. The new series will be made up of annual volumes containing original articles in which the work of the hospital will be reflected. The first volume contains nineteen original articles and 199 pages.

International Hospital Meeting.—The International Hospital Association will hold its fifth congress in Paris, July 6-11. The Federation of Hospital Unions of France has been designated by the Ministry of Public Health to cooperate with the association in planning the program and arrangements. The meeting will occur during the International Exposition in Paris, at which special privileges will be granted to the visitors. Persons attending the congress will benefit by reductions in rates on the French and foreign railroads. The chairman of the committee on arrangements is M. Albert Chenevier, No. 3 Avenue Victoria, Paris IV. Dr. Malcolm T. MacEachern, Chicago, is vice president of the association.

CORRECTIONS

The Bryce Hospital.—The average census of patients in the Bryce Hospital, Tuscaloosa, Ala., for the last fiscal year, was 3,475 instead of 475 as reported in the Hospital Number of THE JOURNAL, March 27, page 1061. The number of beds is 3,261.

Metrazol.—It was erroneously stated in "Poisoning With Barbituric Acid Derivatives" (Queries and Minor Notes, THE JOURNAL, March 13, 1937, p. 908) that metrazol is a soluble camphor derivative. Metrazol is a synthetic, organic chemical compound; namely, pentamethylentetrazol.

Foreign Letters

Criticism of the Protective Measures Against Poison Gas

In the House of Commons, Mr. Pritt said that the government proposed to teach people that, first, they should have gas-proof rooms and use them, and that gas masks would be a second line of defense in the event of such rooms being broken up, or if they happened to be out when the danger began. This was a sham. It had been demonstrated that the walls of ordinary buildings admitted air with such facility that on a windy day a volume of air equivalent to that in the room would enter in fifteen minutes, although the method of gas proofing recommended by the government was carried out. A gas that would kill a person in the open air in six minutes would kill a person in "the gas-proof room" in sixty minutes. It had been said that gas masks were satisfactory, but what was being done for the people who could not wear them? A very large number under the age of 5 years could not wear them and many were too old to wear them.

For the government Mr. Geoffrey Lloyd replied that the methods of gas proofing recommended were taught at the Civilian Anti-Gas School, where gas was discharged against wooden structures erected for demonstration purposes. The government was satisfied that the methods would afford a great measure of protection against any concentration or type of gas that might be expected. The gas masks were specially designed to provide less resistance to breathing than those issued to troops and so could be worn by children and old persons. For infants and young children a special device was being designed.

The most important criticism of the government's measures is a pamphlet issued by "The Cambridge Scientists Anti-War Group." They say: "If the gas is strong enough to injure a man fatally in one hour, then he will receive an equal dose in two and one-half to four hours in his 'gas-proof' room. If the gas is much stronger and would kill in five minutes, the survival time in the room would be only half an hour to one hour. These calculations are made on the assumption that the concentration of the gas remained constant, as it would if a persistent gas were sprayed down the street." They also say that in working-class homes a gas-proof room could seldom be provided, and describe experiments to show that gas masks have only a limited value, and they are doubtful about the possibility of protecting young children. This "group" is accurately described by its title. Its members are all scientists and some of them are eminent. Every one in this country is "anti war," but the term here is used by men who, in some cases at any rate, consider war such an evil that they would not take part in it even to resist aggression. Such persons refused to fight in the war and were called "conscientious objectors." They would not be tolerated in any of the other countries of Europe. They evidently think that one way of preventing war is to persuade the public that the precautions which are being taken are of little value. Their conclusions are not accepted by the government, who suggest political motives.

The Radium Treatment of Cancer

The Holt Radium Institute of Manchester gives in its annual report a review of its results in the treatment of cancer. A generation ago it was generally accepted that most patients admitted to a cancer hospital had but a few months to live and that all which could be done was to nurse and relieve them by administering anodynes. Surgery always worked under the difficulty that operations for any but the earliest stages had

to be extensive. Hence its usefulness was often lost because the patients' fear of the knife made them afraid to seek advice early, when a simple operation might have been successful. When they came later for treatment, a mutilating operation was necessary and the chance of permanent cure was remote. The present report shows that the results of the early treatment of cancer by radiotherapy are extraordinarily good and it even claims that if all early cases were treated cancer in many sites would no longer be a dreaded disease.

In 1933, 1,013 cases of cancer were treated at the institute. The disease affected the mouth, skin, breast, uterus and many other sites. Indeed, the whole range of the common cancers was represented, except those of the digestive system. Oct. 31, 1936, of these 1,013 patients 536, or 53 per cent, were alive. Many of the others had died from cancer, but some from accidents and other diseases to which those of the cancer ages are prone. The chances of survival varied much from patient to patient, being greatest in the early cases, while in many of the advanced cases only palliation was possible.

EPITHELIOMA OF THE SKIN

In 1933, ninety-three cases of epithelioma of the skin were treated; 70 per cent of these patients were alive at the end of October 1936. Survival occurred in 80 per cent of the early cases but in only 16 per cent of the late cases. It is surprising that only fifty-six of the cases were early, as the disease could readily be seen by the patient in its earliest stages.

CANCER OF THE UTERUS

Cancer of the uterus is more difficult for the patient to detect in its early form, for its symptoms then closely resemble those of natural functioning. Of 113 cases only seven were very early and forty-six so early as to offer hope of permanent cure. In the remaining sixty-seven the disease had spread widely beyond the uterus into adjacent structures. Some 33 per cent of these 113 patients with uterine cancer in all stages were alive at the end of October 1936, and 48 per cent of the forty-six with cancer in reasonably early stages.

CANCER OF THE BREAST

Only ten of seventy-one patients had simply small lumps in the breast unaffacting other tissues and not spread to the glands. Of the early cases survival occurred in 70 per cent for three years, but only 20 per cent of those in which the glands were affected and not one of the late cases.

REACHING THE PATIENT

The importance of early treatment being so great, the problem is how to reach the patient early. If the patient lived in Manchester, he almost certainly would be sent directly to the institute or by way of one of the large general hospitals, but in the populous surrounding district there was greater difficulty. The institute therefore established radium clinics in the local hospitals. The patients received radium treatment at the clinics, which were not isolated radium centers but closely bound to the institute, by which treatment was frequently carried out and from which advice in times of difficulty was immediately available. Thus a coordinated system has been established which serves a population of more than two and one-half million.

Physical Training

There is a strong movement in this country for better physical training of the people. The government has issued a pamphlet containing proposals for the development and extension of the present facilities. They include the establishment of advisory councils, committees for the making of grants, subject to the approval of the responsible minister, the founding of a national college for physical training, and grants to the National Playing Fields Association and to the Central Council of Recreative

Physical Training. It is desired to create in the public mind a realization of the value of physical fitness for its own sake and to provide facilities sufficiently attractive to make an effective appeal to the people. The government has decided that any scheme must embrace the whole field of physical culture and therefore include arrangements for increasing the supply not only of gymnasiums but also of playing fields, swimming baths and other means of physical recreation. It is also recognized that many may desire opportunities for physical exercise and recreation not solely as such but as part of a fuller club or community life. The scheme will extend to combined provision of this character.

Public Health Budget Discussion in Parliament

In the discussion Dec. 14, 1936, of the budget of the ministry of public health, the first speaker said that the decrease in population was a vital question for France. It was the result not only of an apparent diminished natality but also of an increase in the mortality rate as compared to other European countries. In Germany there were 147 births and 112 deaths, in England 144 births and 120 deaths, per 10,000 inhabitants, as compared to 163 births and 158 deaths in France. Every effort must be made here to improve sanitary conditions and to prolong life. The second speaker, who represented the newly created government department of physical education, said that, by encouraging sports, much could be accomplished toward decreasing the mortality rate. It appears as though a middle of the road policy on the part of the government between obligatory physical education and free initiative would be preferable. The state should place all its resources at the disposal of private interests in the development of sports in France. The budget of the public health department has been greatly increased this year to permit it to encourage preventive medicine with the aid of the organized medical profession as represented by the syndicates and also to aid existing public and private agencies in their fight against disease. The problem of mental hygiene is a most important one, France being in first place as compared to other countries with respect to the number of insane, there having been an increase of 30 per cent during the past ten years. The minister of public health said that improved economic conditions would do more to increase the annual number of births than the present system of awarding money for large families. A decrease in the mortality rate would soon be followed by an annual increase in the number of inhabitants. This was shown by a glance at the English statistics, which reveal an annual increase of 130,000 inhabitants, as compared to 20,000 in France, although the number of births is equal in the two countries. Hence the fight against alcoholism, tuberculosis, syphilis, insanity and even rheumatism must be intensified.

One of the deputies, Mr. Cousin, objected to a recent (Sept. 26, 1936) decision of the ministry of public health that members of the staffs of public hospitals should not be allowed to accept fees directly from pay patients. He also objected to the order that a pay patient in public hospitals should be allowed to select his own physician, i. e., not be obliged to take a member of the staff as a medical attendant.

In the upper house the statement was made by one of the speakers that it had been hoped that the application of the social insurance law would result in a smaller number of free patients. This had not been found to be the case. After the foregoing discussion, the budget of the department of public health, amounting for 1937 to 1,700,000,000 francs (about \$85,000,000), was voted by both houses of parliament. This is an increase of 600 million francs over the 1936 budget.

Annual Meeting of French Federation of Medical Syndicates

In every department in France, the public relations of the profession are looked after by an association of physicians termed a syndicate. All the latter, eighty-six for France as a whole, are united in a central body, the *Confédération des syndicats médicaux français*, which has its headquarters in a recently purchased building in Paris. The annual meeting of this central organization was held Dec. 18-20, 1936, and presented a special interest because of the presence, as one of the speakers at the banquet, of Mr. Henri Sellier, minister of public health.

The most important subject for discussion at the annual meeting was the organization of preventive medicine. Should it be under the exclusive control of the state with medical officials, or under joint control of the state and the syndicates representing the organized profession or, finally, should the physicians act as individuals under the state? The minister of public health had at first planned to follow the first of these, but after the federation had pointed out that the second idea, i. e., joint action of organized medicine and of the state, was feasible, the minister had agreed to look into such a plan, which might be given a preliminary trial in four of five departments. No efforts to install measures of preventive medicine can be considered efficacious without paying more attention than is at present the case to the questions of alcoholism and inadequate housing conditions. The technical organization ought to be in the hands of the syndicates, or organized profession, according to the secretary's report at this annual meeting.

It is necessary to consider one of the following types of health centers:

1. A complete unit with both administrative and technical divisions in a single or adjacent buildings. In the technical portion would be placed examining rooms, laboratories and radiographic equipment.

2. An administrative unit only, the vaccinations and clinical examination being made at the physician's office.

3. A mixed unit or center including, in addition to administrative offices, some facilities for execution of the state's plan of physical education and encouragement of sports as well as rooms for special medical examinations.

The secretary, Dr. Cibré, was of the opinion that the first of these, i. e., a complete unit, could be employed only in large centers such as Paris or Lyons and hence the second or third units would probably have to be adopted for the majority of the departments.

In the discussion that followed this report, the point was made that periodic health examinations could be better carried out in physicians' offices. Another speaker declared that if the record of every examination must be subjected to the scrutiny of public health officials it would be impossible to guard professional secrecy in many cases. A representative of the radiologic syndicate believed that many patients would go to the health centers and that thus the already rapidly diminishing practice of radiologists would suffer.

Although the opinion of the majority of those who took part in the discussion was favorable to the cooperation of the medical profession and the public health authorities in organizing preventive medicine, preference was given for some plan by which such prophylaxis could be carried out in the offices of the members of the medical syndicates.

In the resolutions voted unanimously, after the reading of the secretary's report, the necessity of a collective contract between the syndicates and the state was emphasized. Such a contract should include the establishment of centers, preferably of the purely administrative type just referred to, the examinations to be made in the offices of the practitioner or specialist.

The next important question was that of hospital care. In France no "mixed" hospitals have existed until recently. Only

one attempt to combine the treatment of free and pay patients under one roof, so to speak, has been made, which will be referred to later. Those unable to pay for hospital care are sent to public hospitals, corresponding to city or county institutions in the United States. These are under the supervision here of the authorities of the respective departments or cities, the expenses of maintenance being paid out of the general taxes. The medical staffs of such hospitals are appointed after a severe competitive examination and hold their positions until they have reached the age of 62 years. In the case of professors, in the medical schools, this age limit is extended to 70 years, unless certain bills now before parliament become law. These "public hospitals" also receive those who are insured under the social insurance law, the expenses of hospital care being paid at an agreed (contract) rate of about \$2 a day by the insurance authorities. The medical staff, up to the present time, has not been allowed to receive any compensation for such "insured" patients.

In addition to the public hospitals treating those unable to pay and the social insurance patients, the only other institutions are those which receive only pay patients. Among these private hospitals (*maisons de santé*) a certain number have made a contract with the social insurance organizations, according to which the insured are cared for at the same rate the insured would have to pay in the public hospitals. It is evident that this lack of mixed or open hospitals in communities not large enough to support a strictly private institution has been keenly felt. If such a private hospital exists in any community, it ought not to have as a competitor the public hospital which receives pay patients.

The sentiment of the meeting was expressed in a motion to the effect that the establishment of wards and rooms for pay patients in public hospitals is permissible only after approval by the authorities and local medical syndicates where existing facilities for private hospital care are inadequate.

A third question discussed at this year's federation meeting was whether medical supervisors employed by the social or private insurance organizations and by railroad companies should be allowed to practice. A motion was passed asking that such a law be enacted, exception being made in the case of physicians who are called on to make examinations as court experts.

Results of Treatment of Dementia Paralytica

France, exclusive of its colonies, is divided for administrative purposes into eighty-six departments. The official representative of the central government (situated in Paris) in each department is the prefect. In the energetic antivenereal campaign which the present minister of public health is carrying on, every effort is being made to check, so far as possible, the source of contagion in the form of supervision of prostitutes by the public health officials instead of the police, as is at present the case. A bill will be introduced shortly in parliament to make such a change throughout France. In its circular of Dec. 10, 1936, the ministry of public health addressed to the prefects of all departments a request that they have a questionnaire filled out by superintendents of insane asylums and local antivenereal workers to ascertain whether the use of modern therapeutic measures such as arsenical and bismuth preparations, and of malaria therapy and the perfection of serologic diagnosis, has had any influence on the frequency of dementia paralytica in the respective departments. Information is also desired as to whether the clinical picture has been changed and how often the terminal stages of the disease are observed. The necessity for all those taking part in the antivenereal campaign to trace the number of those (wife and children) who have been infected by a syphilitic husband or father is also to be ascertained. Early recognition of such cases can now be more easily carried out since the antivenereal forces have been better organized by the ministry of public health.

Extension of Insurance Against Occupational Diseases

National legislation with regard to occupational disease insurance has recently been substantially reinforced. Sufferers from the most common and dangerous occupational malady, pneumoconiosis, have heretofore received compensation only if the disease was acquired while the insured was employed in one of a certain specified list of occupations. Now disability allowance is granted all pneumoconiosis patients who have become ill while engaged in any insurable occupation. In the sphere of occupational skin diseases the insurance laws have likewise been considerably extended. Here too previous restrictions have been removed and a group of occupational diseases not heretofore covered by industrial insurance is now included within its framework.

It is interesting to note in this connection just which disorders are classed as occupational. A disease is recognized as occupational only if it was contracted by the insured in the course of actual industrial employment. Listed as occupational diseases are diseases originating from contact with lead, phosphorus, mercury, arsenic, manganese and their compounds, benzene and its homologues, nitrobenzene compounds and amino compounds of benzene or its homologues and their derivatives, halogen-hydrocarbons of the aliphatic series, carbon disulfide and hydrosulfuric acid. Excepted from the list are skin diseases that can be termed occupational only so far as they are manifestations of one of the general pathologic conditions caused by absorption of the noxious substances into the organism or if they are included in the following categories of skin diseases: skin diseases from contact with carbon monoxide, roentgen rays and radioactive substances; skin cancer or skin lesions that tend to become cancerous resulting from contact with soot, paraffin, tar, anthracene, pitch and similar substances; affliction with cancer or other neoplasms as well as changes in the mucosa of the urinary tract by aromatic amine; severe or repeatedly relapsing cases of skin disease that compel the worker to change his occupation or to give up gainful employment; disturbances of the musculature, bones and joints caused by working with compressed air tools; severe silicosis as well as silicosis in connection with pulmonary tuberculosis if the entire illness is severe and the pneumoconiotic alterations have caused the tuberculosis to assume an active progressive course, and, lastly, severe asbestosis. Accident insurance is made to cover all the foregoing diseases if the insured is gainfully employed in any recognized industry. The only other occupational diseases recognized as such are those acquired in especially designated industries: pulmonary cancer from the manufacture of chromates, for example, disturbances of the lower respiratory passages and the lungs from inhalation of ground basic slag in the mills or from the mixing, storage and transportation of such slag, malignant lymphosarcoma of the lungs present among workers in the ore mines of Schneeberg, Saxony; deafness or disturbance of the hearing bordering on deafness produced by noise in the metallurgic industries, gray cataract acquired in glass factories, ironworks and smelters; verminosis of mine workers, tropical diseases, typhus and scurvy acquired by persons engaged in maritime and aerial navigation or in business abroad; finally, infections contracted in hospitals and other institutions for the care of the sick as well as in the conduct of welfare service and health service and in diagnostic and experimental laboratories. If there exists for an insured worker the danger that continuance in his employment will mean the beginning, the recurrence or the exacerbation of an occupational disease, he will then be compelled to give up this occupation and will receive a certain compensation for the loss of his earnings. With regard to examination by the industrial physician in

charge, exact standards are prescribed in order to assure quick procedure. If a doctor establishes that an insured worker is suffering from a definite occupational disease or if the worker exhibits symptoms that would justify the suspicion of such a disease, an official report must be submitted at once. A physician may be punished for failing to report the result of his observations promptly.

Cancer and Race

Prof. Walther Fischer, pathologic anatomist of the University of Rostock, has reported the results of his own investigation of cancer and race before the medical society there. The approach to this problem is still difficult, as the mortality statistics in various countries are not worked up according to any uniform system. Moreover, Fischer adds, despite the fact that they emanate from official sources, the data are often wholly unreliable. The obduction material of the pathologic institute is accurate enough to be sure, but since the subjects all belong to a special group, namely, hospital patients, such statistics can scarcely represent a fair cross-section of the population. For a comparative study of the question, which embraces tropical countries, variations in the age of a given population must also be taken into account. Due consideration of all these criteria lead one to conclude that the data at present extant form no sound basis for any comparative evaluation. Within these limitations, then, one may hazard the following tentative conclusions:

The various European races present no manifest difference with regard to carcinoma. The Jewish population within the larger cities of Europe shows the same incidence of cancer and only occasionally differences with regard to the incidence of the localization. In the United States, according to Fischer's statistics, the incidence of cancer is the same among white women and Negroes, whereas the disease is 40 per cent less frequent among male Negroes than among white men. Among the Japanese and apparently among the Chinese as well, cancer is about as prevalent as among Europeans. Manifest differences in the most common seats of the cancer exist, however, among the yellow races, the Malays and the Negroes of South Africa. In the yellow race, primary carcinoma of the liver (with cirrhosis) is most frequently encountered. Among the Malays, cancer of the stomach is extremely rare. Sarcomas are much more common among members of the colored races than among white persons. Fischer believes that the differences observed in the incidence and location of cancer are to be attributed to environmental influences and not to hereditary factors.

AUSTRALIA

(From Our Regular Correspondent)

Feb. 10, 1937.

Imports of Dangerous Drugs

According to official figures the Australian consumption of cocaine is higher per head than that of any other English-speaking country. Australia's consumption of cocaine is now shown at 12.4 Kg. per million of population, compared with

Consumption of Morphine and Heroin per Million of Population

	Morphine	Heroin
Australia	13.9	3.31
Britain	13.85	1.18
Canada	11.84	2.13
United States	18.54	Negligible
New Zealand	11.60	1.99

5.29 in Britain, 4.89 in Canada, 6.82 in the United States and 7.12 in New Zealand. An increasing use of cocaine by dentists is shown. The consumption of morphine and heroin per million inhabitants is also high. The figures are given in the accompanying table. In Australia, heroin can be imported only through a government department, and the drug is then dis-

tributed to licensed importers. Control of the importation of all harmful drugs is vested in the commonwealth government, which issues licenses to approved importers; but the importers must secure a permit for each individual shipment of such drugs, with the exception of heroin. Further investigations are being made with a view of endeavoring to trace the reason for the wide variation in these figures.

The Moppett Test for Cancer

Working under the control of the Cancer Research Committee of the University of Sydney, Dr. Warnford Moppett has devised a blood test for the presence of cancer, details of which are given in the *Journal* of the Cancer Research Committee of the University of Sydney for May 1936. The originator claims that his test is 80 per cent correct for positive cases. D. A. Welsh, professor of pathology in the University of Sydney, considers that the test has a scientific significance, and he quotes the results of an independent series of positive tests, which were 92 per cent correct. The tests were made on patients having cancers in many different anatomic sites, many of the cancers being in an early stage and quite small. The test may be summarized thus: The blood to be tested and blood from a healthy control are placed in opposite ends of a special diffusion vessel, which is filled with physiologic solution of sodium chloride after the bloods have clotted. A fragment of mouse tumor (sarcoma) is placed on a glass plate, which is then inverted over the diffusion vessel so that the tumor fragment comes midway between the two blood clots. An initial reading (drawing) is taken of the periphery of the mouse tumor fragment. The diffusion vessel is then incubated at 37 C., and readings are taken at one hour and at twenty-four hours.

In a negative reaction there is a more or less symmetrical "outwandering" of cells from the sarcoma fragment. In a positive test for cancer there is a definite "sweeping" movement of the mouse sarcoma cells away from the cancerous patient's blood. Dr. Moppett has found that a minor degree of repulsion of the cells may be seen when the test blood is taken in some inflammatory conditions; but this was not read as a positive reaction for cancer.

Dr. Moppett has suggested some improvements on his original technic and has given the results of twenty-three tests, made on unknown bloods, in addition to the thirty tests published in his earlier paper. Of these twenty-three tests, eight gave a positive reaction for cancer; and of these eight positives five were correct and three were incorrect according to the biopsies. Admittedly that is a poor result, which shows that, even in the experienced hands of Dr. Moppett himself, the difficult technic is far from being reliable as yet. Nevertheless, both in its successes and in its failures, Dr. Moppett's test for cancer has raised questions of great scientific interest and promising practical value.

Dr. E. F. Thomson was commissioned by the Cancer Research Committee of the University of Sydney to make an independent investigation of the Moppett test for cancer. After preliminary tests made in conjunction with Dr. Moppett, Dr. Thomson undertook 100 additional tests, for the conduct and interpretation of which he was personally responsible. These experiments were carried out with great care and attention to detail; for example, three diffusion vessels were prepared for each test to eliminate accidental error. The results were unexpectedly good. Positive reactions for cancer were given by thirty-six test bloods, and thirty-three of these were taken from patients clinically cancerous, while only three came from patients clinically noncancerous. In twenty-five patients the clinical diagnosis was confirmed by biopsy; in seven patients a biopsy was omitted but the clinical diagnosis was regarded as obvious. It is important to note that these thirty-three cor-

rect positive tests for cancer were given by patients in comparatively early stages of cancer, before anemia or wasting had become apparent. The three incorrect positive tests for cancer are discussed at length, and there is evidence that all three patients had probably developed cancer at some time. As this type of success and of failure is the critical test in serologic diagnosis, these results are encouraging.

The available evidence warrants further critical examination of the test, including the question whether the mouse sarcoma (tumor S37 of the Imperial Cancer Research Fund) is the best indicator.

BELGIUM

(From Our Regular Correspondent)

Feb. 12, 1937.

International Congress on the Campaign Against Cancer

The second International Congress on the Scientific and Social Campaign Against Cancer, which represented a real landmark in the fight against cancer, was held at Brussels. The king honored the opening ceremonies by his presence, thus once more attesting his personal interest in the progress of medical science. More than 500 physicians representing forty-three countries met in the great hall of the Palais des académies. After the roll call of delegates present had been broadcast in six different languages, Dr. Lerat spoke from the chair. In a speech filled with lofty sentiments he pointed out that scientists the world over are bound together in a common determination to combat cancer. The search for the basic causes of cancer is the central problem about which all other problems gravitate. The chairman ended his address with the following peroration: "Since cancer is to be combated by scientific means, I for one wish that Science, the daughter of Peace, would no longer be compelled to serve the purposes of that other destructive force and slayer of men. May peace on earth to men of good will shine forth like a rainbow's arc signaling the end of international tempests and assure to the scientist that tranquillity so requisite for the creative endeavor and the discovery of truth."

The second speaker was Emile Vandervelde, minister of public health, who described Belgium's rôle in the anticancer campaign. Cancer research centers and clinics, all provided with the most modern equipment, have been established by the four Belgian universities. The practicing physician and the visiting nurse have delicate and frequently ungrateful but indispensable services to perform in connection with the organized campaign. There is great need for a campaign of public education to counteract the erroneous popular ideas with regard to the mysterious nature of cancer. The physician too should be taught to renounce his personal interests in order to collaborate in this common cause. In a peroration in keeping with his great forensic talent, Vandervelde said: "We are witnessing, alas, a worldwide speeding up of the armaments race, a situation charged with incredible menace. But this congress loudly proclaims the fact that, fostered by mutual example, there is developing a race in the scientific armament that points toward peace as surely as that other race points toward war. In the words of Duhamel, there is an international language, the language of suffering; and one may hope that the day is at hand wherein the prophecy of Pasteur shall be verified: science and peace shall one day triumph over ignorance and war."

Every aspect of our present knowledge of cancer was touched on in the course of the various sessions. Only the more noteworthy discussions are here summarized.

CHEMICAL COMPOUNDS AS CANCERIGENIC AGENTS

E. L. Kennaway, J. W. Cook, G. A. D. Haslewood, C. L. Hewett, I. Hieger and W. V. Mayneord of London classified

for the South Boston health unit; for many years medical supervisor of the parochial schools of Boston; formerly on the staff of St. Margaret's Hospital; aged 59; died, February 11, of bronchopneumonia.

Benjamin Baker Moeur, Tempe, Ariz.; Arkansas Industrial University Medical Department, 1896; governor of Arizona, 1933-1937; member of the Constitutional Convention of Arizona in 1910; president of the Arizona State Board of Health, 1933-1937; for twelve years secretary of the board of education of the Arizona State Teachers College; aged 67; died, March 16, of coronary occlusion.

Charles Rufus Skinner, Hudson, N. Y.; University of Vermont College of Medicine, Burlington, 1899; secretary of the Columbia County Medical Society for ten years; deputy health commissioner of Columbia County; school physician; aged 65; formerly on the staff of the Hudson City Hospital, where he died, January 1, of lobar pneumonia and mitral insufficiency.

James Benjamin Dougherty, Canton, Ohio; Ohio Medical University, Columbus, 1903; member of the Associated Anesthetists of the United States and Canada; past president of the Stark County Medical Society; served during the World War; on the staff of the Aultman Hospital; aged 57; died, January 22, in Naples, Fla., of coronary thrombosis.

William Merritt Conant, Boston; Harvard University Medical School, Boston, 1884; fellow and a founder of the American College of Surgeons; member of the Massachusetts Medical Society and the American Association of Anatomists; honorary consulting surgeon to the Massachusetts General Hospital; aged 81; died suddenly, February 18.

Lloyd P. Warren Sr., Wichita, Kan.; Beaumont Hospital Medical College, St. Louis, 1900; fellow of the American College of Surgeons; on the staff of the Wichita Hospital; an associate editor and formerly editor of the *Medical Bulletin*, official publication of the Sedgwick County Medical Society; aged 66; died, January 17, of carcinoma.

Thor Christian Rothstein, Chicago; Karolinska Mediko-Kirurgiska Institutet, Stockholm, Sweden, 1897; professor emeritus of neurology, Rush Medical College; aged 72; on the consulting staff of the Augustana Hospital and on the staff of the Presbyterian Hospital, where he died, February 19, of arteriosclerosis and coronary thrombosis.

Joseph William Scannell, Lewiston, Maine; University of Maryland School of Medicine, Baltimore, 1906; member of the Maine Medical Association; formerly fire commissioner; on the staff of the Central Maine General Hospital; chairman of the cancer committee of the Maine Medical Association; aged 53; died, January 16, of heart disease.

John Alexander Houston, Northampton, Mass.; Medical School of Maine, Portland, 1880; member of the Massachusetts Medical Society, the American Psychiatric Association and the New England Society of Psychiatry; for many years superintendent of the Northampton State Hospital; aged 77; died, January 18, of coronary thrombosis.

Howard Jay Teller, Rome, N. Y.; Baltimore University School of Medicine, 1898; past president of the Oneida County Medical Society; formerly county coroner, alderman and county physician; on the staff of the Rome Hospital and Murphy Memorial Hospital; aged 61; died, January 28, of coronary thrombosis.

Ira Jackson Tatum, Union City, Tenn.; University of Tennessee Medical Department, Nashville, 1900; served during the World War; formerly connected with the U. S. Veterans Bureau; aged 71; on the staff of the Edwin W. Cocke Sanatorium, Memphis, where he died, January 4, of coronary occlusion.

Harry Hubbard Brookhart, Columbus, Kan.; Marion-Sims College of Medicine, St. Louis, 1895; president of the Cherokee County Medical Society; served during the World War; on the staff of the Maude Norton Memorial City Hospital; aged 64; was killed, January 29, in an automobile accident.

Emory William Reisinger, Fairfax, Va.; Georgetown University School of Medicine, Washington, D. C., 1893; member of the faculty at his alma mater, 1895-1917, when he resigned as assistant professor of anatomy; aged 65; died, January 20, in Staunton of mitral regurgitation and bronchopneumonia.

Alpheus Freeman, New York; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1882; member of the Medical Society of the State of New York; for many years on the staff of the Presbyterian Hospital; aged 77; died, January 25, in a local hospital.

Charles Hunt, Clinton, Ky.; University of Nashville (Tenn.) Medical Department, 1900; member of the Kentucky State Medical Association; served during the World War; county health officer; bank president; aged 62; died, January 24, in the Illinois Central Hospital, Paducah.

Halvor Holte, Crookston, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1893; member of the Minnesota State Medical Association; fellow of the American College of Surgeons; aged 79; died, January 2, in the Bethesda Hospital, of pneumonia.

Samuel James Blanchflower Collins, Whiteville, N. C.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1913; L.R.C.P. Edinburgh, 1930; L.R.C.S. Edinburgh, and L.R.F.P.S. Glasgow, 1930; aged 62; died, January 20, in a hospital at Durham, of angina pectoris.

Hugh J. Coll, Connellsville, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1895; member of the Medical Society of the State of Pennsylvania; aged 67; on the staff of the Connellsville State Hospital, where he died, January 27, of cerebral thrombosis.

Frederick Erastus Hamlin, Brooklyn; University of the City of New York Medical Department, 1893; member of the Medical Society of the State of New York; for many years an examining physician for the Prudential Life Insurance Company; aged 71; died, January 29.

George B. M. Free, York, Pa.; University of Maryland School of Medicine, Baltimore, 1883; University of Pennsylvania Department of Medicine, Philadelphia, 1884; formerly on the staff of the Danville (Pa.) State Hospital; aged 75; died, January 16, of pneumonia.

Alpheus Luther Pollard, Sedalia, Mo.; State University of Iowa College of Homeopathic Medicine, Iowa City, 1893; member of the Missouri State Medical Association; formerly city physician; aged 81; died, January 2, of essential hypertension and hemiplegia.

Spencer S. Wade, Morgantown, W. Va.; Jefferson Medical College of Philadelphia, 1884; member and past president of the West Virginia State Medical Association; for many years a member of the board of education; aged 79; died, January 22, of internal hemorrhage.

Myron Henry Davis, Saugus, Mass.; Harvard University Medical School, Boston, 1885; health officer of Saugus; school physician; on the staff of the Lynn (Mass.) Hospital; aged 74; died, January 21, of bronchopneumonia, arteriosclerosis and chronic myocarditis.

Phau Rivers Outlaw, El Paso, Texas; Bellevue Hospital Medical College, New York, 1893; member of the State Medical Association of Texas; served during the World War; formerly health officer of El Paso; aged 67; died, January 12, of pulmonary tuberculosis.

Leland Grant Hewitt, Northwood, Iowa; Rush Medical College, Chicago, 1892; member of the Iowa State Medical Society; past president of the Worth County Medical Society; for many years county coroner; aged 70; died, January 31, of pulmonary abscess.

Andrew J. Minaker, San Francisco; Hahnemann Hospital College of San Francisco, 1899; College of Physicians and Surgeons of San Francisco, 1902; served during the World War; aged 60; died, January 16, in the Franklin Hospital, of bronchopneumonia.

George Kirby Sims, Bolivar, Mo.; Northwestern University Medical School, Chicago, 1922; secretary of the Dallas-Hickory-Polk Counties Medical Society; aged 56; died, January 24, in St. John's Hospital, Joplin, of meningitis and lobar pneumonia.

Erskine Marshall Barnes, Lincoln, Neb.; Lincoln Medical College of Cotner University, Lincoln, 1903; veteran of the Spanish-American and World wars; on the staff of the Veterans Administration Facility; aged 60; died, January 4, of coronary thrombosis.

Charles Sumner Neer, Vinita, Okla.; St. Louis University School of Medicine, 1906; formerly part owner of the Vinita Hospital; aged 57; died, January 22, in St. Anthony's Hospital, Oklahoma City, following an operation for gastric ulcer.

Forest Clyde Van Hook, Mount Pulaski, Ill.; Northwestern University Medical School, Chicago, 1913; for several years a member and president of the board of education; aged 49; died, January 29, in Tucson, Ariz., of diabetes mellitus.

Robert Anderson Taylor, Topeka, Kan.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1906; served during the World War; aged 55; on the staff of the Christ's Hospital, where he died, January 31, of pneumonia.

Evan Jones Smith Ⓢ Irvington, N. Y.; University of Buffalo School of Medicine, 1895; medical officer of the school district; on the staff of the Dobbs Ferry (N. Y.) Hospital; aged 70; died, February 12, of carcinoma of the sigmoid.

Harry Edwin Burdick Ⓢ David City, Neb.; Omaha Medical College, 1899; fellow of the American College of Surgeons; served during the World War; co-founder of the David City Hospital; aged 59; died, January 12, of lobar pneumonia.

Jay Logan Magill, Holdrege, Neb.; University Medical College of Kansas City, Mo., 1900; member of the Nebraska State Medical Association; aged 58; died, January 23, at the Holdrege Hospital, of bronchopneumonia and influenza.

Addison Morgan, Fall Brook, Calif.; University of Michigan Homeopathic Medical School, Ann Arbor, 1881; formerly coroner of San Diego County; veteran of the Spanish-American War; aged 78; died, January 8, of chronic myocarditis.

Colin McFarquhar Reed Ⓢ Youngstown, Ohio; University of Pittsburgh School of Medicine, 1915; served during the World War; aged 49; died, January 23, in the North Side Unit of the Youngstown Hospital, of intestinal obstruction.

John Thames Ⓢ Charleston, W. Va.; Louisville (Ky.) Medical College, 1894; served during the World War; county health officer; formerly health officer of Little Rock; aged 65; died, January 11, of arteriosclerotic heart disease.

Charles Weber, Cincinnati; Cincinnati College of Medicine and Surgery, 1881; aged 79; died, January 28, in the Good Samaritan Hospital from the effects of carbon monoxide poisoning caused by a defective furnace in his home.

Morton Earl Fox, Uncasville, Conn.; Long Island College Hospital, Brooklyn, 1893; member of the Connecticut State Medical Society; health officer of Montville; aged 66; died, January 2, of bronchopneumonia and anemia.

Isaiah Alpheus Boyd, Washington, D. C.; Meharry Medical College, Nashville, Tenn., 1890; Howard University College of Medicine, Washington, D. C., 1891; aged 71; died, January 23, in the Freedmen's Hospital, of pneumonia.

Bernard Joseph Wess, Baltimore; Baltimore Medical College, 1905; member of the Medical and Chirurgical Faculty of Maryland; aged 54; on the staff of St. Joseph's Hospital, where he died, January 9, of coronary thrombosis.

Frank Estil Casburn, Holly, Colo.; University of Kansas School of Medicine, Kansas City, 1906; member of the Colorado State Medical Society; aged 57; died, January 29, in Lamar, of hypertension, myocarditis and nephritis.

Joseph Griffin Waldrop, Hot Springs National Park, Ark.; Memphis (Tenn.) Hospital Medical College, 1901; member of the Arkansas Medical Society; aged 62; died, January 17, of cerebral hemorrhage and hypertension.

Thomas Quincy Ray, Andalusia, Ala.; Atlanta (Ga.) Medical College, 1895; member of the Medical Association of the State of Alabama; aged 71; died suddenly, January 3, of cerebral hemorrhage and hypertension.

Horace Snoad Cooper, Denver; Denver College of Medicine, 1900; member of the Colorado State Medical Society; served during the World War; aged 66; died in January, at St. Luke's Hospital, of pneumonia.

Edwin Henry Harvey Ⓢ Atlantic City, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1895; aged 67; died, February 22, in the Pennsylvania Hospital, Philadelphia, of cerebral hemorrhage.

Bryant Smith, Oconomowoc, Wis.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1891; aged 71; died, January 7, in Milwaukee, of rupture of the aorta and arteriosclerosis.

Howard Mendenhall Buck, Boston; Harvard University Medical School, Boston, 1882; member of the Massachusetts Medical Society; aged 80; died, January 11, of bronchopneumonia and cerebral thrombosis.

Arthur Conant Poe, Cleveland; Long Island College Hospital, Brooklyn, 1885; a medical examiner for the Metropolitan Life Insurance Company for many years; aged 72; died, January 22, of cerebral sclerosis.

Thomas Nicholas Burke, Elkhorn, Neb.; John A. Creighton Medical College, Omaha, 1904; for many years a member of the village board and school board; aged 61; died, January 5, of carcinoma of the cecum.

Joseph Henderson Coffee, Arcadia, Fla.; Atlanta College of Physicians and Surgeons, 1910; formerly member of the state legislature; aged 58; died, January 25, in a local hospital, of influenza and pneumonia.

Norman H. Haviland, Fulton, N. Y.; Eclectic Medical College of Pennsylvania, Philadelphia, 1872; Homeopathic Hospital College, Cleveland, 1873; aged 92; died, February 13, of carcinoma of the prostate.

Edward Williamson Perkins, Petersburg, Va.; University of the South Medical Department, Seawane, Tenn., 1903; member of the Medical Society of Virginia; aged 59; died, January 23, of heart disease.

Edward Otis Parker Ⓢ Pendleton, Ore.; Willamette University Medical Department, Salem, 1903; formerly physician in the Indian Service; aged 64; died, January 21, of coronary occlusion and sclerosis.

William K. Shedd, Columbia, Tenn.; University of Tennessee Medical Department, Nashville, 1887; formerly secretary of the Maury County Medical Society; aged 78; died, January 8, of hemiplegia.

William Smith Crosby, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1900; aged 59; died, January 15, in the Philadelphia General Hospital, of cirrhosis of the liver.

Joseph Aloysius Ball, Los Angeles; John A. Creighton Medical College, Omaha, 1898; formerly a practitioner in Stuart, Iowa, and Council Bluffs, Iowa; aged 64; died, January 22, of pneumonia.

David William Rosen, Boston; Tufts College Medical School, Boston, 1910; member of the Massachusetts Medical Society; aged 57; died, January 3, in the Beth Israel Hospital, of hypertension.

Ernest Dalton Richmond, Reading, Mass.; University of Vermont College of Medicine, Burlington, 1894; member of the Massachusetts Medical Society; aged 67; died, January 4, of heart disease.

Robert Hamilton Folk, Belton, S. C.; University of Maryland School of Medicine, Baltimore, 1916; served during the World War; aged 48; died, January 17, of bronchopneumonia and myocarditis.

Hiram S. Jones, Carroll, Ohio; University of Wooster Medical Department, Cleveland, 1879; aged 87; died, January 2, in the McMillen Sanitarium, Columbus, of pneumonia and arteriosclerosis.

Adelbert DeRoy Haines, Rochester, N. Y.; Eclectic Medical Institute, Cincinnati, 1884; aged 76; died, January 21, in the Highsmith Hospital, Fayetteville, N. C., of myocarditis and prostatectomy.

S. Claude Andrus Ⓢ Rockford, Ill.; Northwestern University Medical School, Chicago, 1897; aged 64; formerly on the staff of the Rockford Hospital, where he died, January 12, of pneumonia.

Ephraim W. Ellis, Dunbarton, S. C.; University of Georgia Medical Department, Augusta, 1891; aged 74; died, January 3, in Augusta, Ga., of hypertrophy of the prostate and bronchopneumonia.

Estella Clark Carpenter, Chicago; Jenner Medical College, Chicago, 1903; member of the Illinois State Medical Society; aged 69; died, January 26, of carcinoma of the intestine and lung.

James E. Cunningham, Chicago; Northwestern University Medical School, Chicago, 1896; aged 48; died, January 27, in the Veterans Administration Facility, Hines, Ill., of coronary occlusion.

Thomas W. Wilkinson, San Antonio, Texas (licensed in Texas, under the Act of 1907); formerly a medical missionary; aged 67; died, January 8, of coronary thrombosis and arteriosclerosis.

Philip Wolfman, New Brunswick, N. J.; Albany (N. Y.) Medical College, 1903; aged 64; died, January 3, in the General Hospital, Perth Amboy, of cerebral thrombosis and diabetes mellitus.

Henry Bradford Babbitt, Brockton, Mass.; Boston University School of Medicine, 1888; aged 71; died, Dec. 20, 1936, in Foxboro, of Adams-Stokes' syndrome and cerebral arteriosclerosis.

Mora Simeon Bulla, Elizabeth City, N. C.; Miami Medical College, Cincinnati, 1905; on the staff of the Albemarle Hospital; aged 55; died, January 28, of hemiplegia and hypertension.

James Dallas Liles, Vanceburg, Ky.; University of Louisville Medical Department, 1905; member of the Kentucky State Medical Association; aged 55; was found dead, January 16.

Leonard Erhard Bartz Ⓢ Windsor, Colo.; Denver College of Physicians and Surgeons, 1903; owner of the Bartz Memorial Hospital; aged 63; died, January 18, of angina pectoris.

James Franklin Davies, Callaway, Neb.; Omaha Medical College, 1893; member of the Nebraska State Medical Association; aged 66; died, January 3, of coronary occlusion.

Josiah Green Smith, Port Arthur, Texas; Louisville (Ky.) Medical College, 1888; member of the State Medical Association of Texas; aged 80; died, January 3, of erysipelas.

Elias John Helgesen, Evansville, Wis.; College of Physicians and Surgeons, Keokuk, Iowa, 1893; aged 70; died, January 22, of uremia, nephritis and heart disease.

Hugh Hagan Lenahan, New Hartford, N. Y.; Syracuse University College of Medicine, 1903; aged 58; died, January 17, of lobar pneumonia and chronic nephritis.

John Alfred Freeze, Bunker Hill, Ind.; Hospital College of Medicine, Louisville, Ky., 1897; aged 69; died, January 6, of carcinoma of the prostate and myocarditis.

John Jackson Johnson, Calhoun, Ga.; Emory University School of Medicine, Atlanta, 1932; aged 29; died, January 9, of injuries received in an automobile accident.

Herbert B. Wright, Skaneateles, N. Y.; Syracuse University College of Medicine, 1881; aged 85; died, January 13, of cerebral hemorrhage and arteriosclerosis.

Robert Algie ♂ **Clay Center**, Kan.; Barnes Medical College, St. Louis, 1899; served during the World War; aged 60; died, January 25, of splenomyelogenous leukemia.

Sarah Gaston Frack, Niles, Ohio; Cleveland University of Medicine and Surgery, 1895; aged 67; died, January 31, in Los Angeles, of a cerebral hemorrhage.

George Edward Norton ♂ **Cambridge**, Mass.; University of Vermont College of Medicine, Burlington, 1899; aged 72; died, January 6, of cardiorenal disease.

Harvey Edmund Colvin, Burlington, Vt.; Chicago Homeopathic Medical College, 1880; aged 82; died, January 10, of chronic myocarditis and nephritis.

John Volmer, Wichita, Kan.; University of Arkansas School of Medicine, Little Rock, 1913; aged 59; died, January 15, of cerebral hemorrhage.

Albert Lincoln Winslow, Danville, Va.; Leonard Medical School, Raleigh, N. C., 1893; aged 70; died, January 13, of progressive muscular atrophy.

Sadie Monahan, Dayton, Ohio; Laura Memorial Woman's Medical College, Cincinnati, 1896; aged 78; died, January 29, of cerebral hemorrhage.

Clyde D. Schurtz ♂ **Alexandria**, Ind.; Rush Medical College, Chicago, 1885; aged 77; died, January 27, in St. John's Hospital, Anderson.

Harry Lovejoy Coleman ♂ **Farragut**, Iowa; Rush Medical College, Chicago, 1891; aged 70; died suddenly, January 23, of angina pectoris.

Millard Fillmore Funk, Mowrystown, Ohio; Eclectic Medical Institute, Cincinnati, 1884; aged 82; died, January 27, of Addison's disease.

Kate Z. Horner Jacobson, Sioux City, Iowa; Sioux City College of Medicine, 1896; aged 68; died, January 6, of bilateral lobar pneumonia.

Wallace C. Quinn, Brockway, Pa.; College of Physicians and Surgeons, Baltimore, 1884; aged 76; died, January 25, of heart disease.

Edmon Arthur Gilson, San Antonio, Texas; Toledo Medical College, 1905; aged 64; died, January 23, of coronary thrombosis.

William H. Dempsey ♂ **Alton**, Ill.; Missouri Medical College, St. Louis, 1898; aged 65; died, January 29, of bronchopneumonia.

George Whitefield Hopkins, Cleveland; Cleveland Medical College, 1896; aged 64; died, January 19, of chronic interstitial nephritis.

John Fahrner Sr., Joliet, Ill.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1882; aged 82; died, Dec. 29, 1936.

Israel Goldwin Smith, Ottawa, Ont., Canada; University of Toronto Faculty of Medicine, 1896; died, Dec. 25, 1936.

Edward J. Taggart ♂ **Bremerton**, Wash.; Omaha Medical College, 1888; aged 73; died, January 16, of pneumonia.

Elizar Kent Bailey, Ogallala, Neb.; Chicago Medical College, 1877; also a minister; aged 88; died, January 11.

Albert James Tilton, Brooklyn; College of Physicians and Surgeons of Chicago, 1890; aged 73; died, January 7.

Cicars Camp, Patmos, Ark. (licensed in Arkansas in 1903); aged 60; died, January 28.

Bureau of Investigation

J. R. BRINKLEY AND HIS FORMULA NO. 1020

At various times there arises in the history of quackery some extraordinary individual before whose accomplishments all previous charlatans fade into insignificance. In the history of quackery, the names of Elisha Perkins, Zeileis, Asuero, Abrams, Brinkley and Baker loom large. Many of those named have gone to the quack's ultimate reward, proving at the same time in some instances that the wage of sin is not only death. The career of John R. Brinkley is not yet ended. From the time when he first appeared on the American scene, through the period of his residences in New York and Kansas, and to that of his present domicile in Texas, he has stood out in bold relief even among such fascinating competition as the world now affords. The latest development in his career is the promotion of formula No. 1020. This concoction, it seems, is given to patients who have previously submitted themselves to the personal ministrations of J. R. Brinkley and who are willing to spend sums like \$100 for six ampules of the new remedy, in order that they may be still further benefited by his extraordinary talents.

Various physicians have submitted to the Chemical Laboratory of the American Medical Association ampules labeled:

"20 c. c. plus

Formula No. 1020

Prepared especially for

J. R. Brinkley, M.D.

Del Rio, Texas"

Thus a Mississippi physician writes:

"A few days past I wrote to you relative to the Dr. Brinkley operation and treatment . . . This morning a man came in to see me with a box of ampules, requesting that I give him two per day intravenously. He had been to Dr. Brinkley but failed to remain until the treatment was completed. I am sending you one of these ampules for analysis. The container states that it is made by Val Verde Co. of Del Rio, Texas, for Dr. Brinkley. I have refused to administer the same unless the formula is furnished."

A Nashville, Tenn., physician states:

"We are mailing you under separate cover an ampule of liquid which John R. Brinkley of Del Rio, Texas, sells to patients at the rate of six ampules for \$100. They are given intravenously. We are interested to know what the chemical analysis shows to be its contents. Any information you can furnish us will be appreciated."

From Wyoming a physician inquires:

"I am mailing you under separate cover an ampule of medicine used by Dr. J. R. Brinkley. I have had several requests by some of my patients to administer it to them, intravenously, and before doing so would like to know what this ampule contains . . ."

From a Wisconsin physician:

"Under separate cover I am sending by first class mail the ampule sent by Brinkley. Any information you can give me regarding its contents will be appreciated."

The laboratory submits the following report:

LABORATORY REPORT

"The physical appearance of each ampule resembled the others, though the sources were different. Each ampule contained about 20 cc. of a clear solution having a sky blue color, odorless, and practically tasteless. The density of the liquid was 0.9985 at 25 degrees. This is practically the same as that of water at 25 degrees (0.9971). On evaporating the solution there remained a very small residue, bluish in color, amounting to 0.004 per cent and in terms of sulfated ash was 0.003 per cent. Spectrographic analysis indicated the presence in extremely small amounts of such metallic constituents as silicon, zinc, magnesium, iron, copper, sodium and calcium. Macro- and micro-chemical investigation indicated that the organic blue material was a dye of the indigo type containing a very small amount of zinc. Synthetic solutions containing indigo dyes were prepared, based on the foregoing information. Each contained 0.001 Gm. of the dye to 100 cc. of distilled water. The

colors were matched with each other and found to correspond in shade and hue to that of the Brinkley ampules. Photospectrographic examinations (absorption spectra) corroborated the chemical analysis suggesting the presence of the indigo dye.

"From the foregoing it is concluded that a solution having essentially the same characteristics as that labeled 'Formula No. 1020, J. R. Brinkley, M.D.' may be prepared by dissolving one part of indigo in 100,000 parts of water. Such a solution is essentially water to which has been added a dash of blue dye."

The kind of genius capable of taking a body of water like Lake Erie, coloring it with a dash of bluing and then selling the stuff at \$100 for six ampules represents a type which all the world up to now has never been able to equal. John R. Brinkley is the absolute apotheosis in his field. Centuries to come may never produce again such blatancy, such fertility of imagination or such ego.

Correspondence

"THE PROBLEM OF SCHOOL MEDICAL AND DENTAL SERVICE"

To the Editor:—The importance of Dean Smiley's article (THE JOURNAL, February 6) on "The Problem of School Medical and Dental Service" cannot be overestimated. It is properly stated that the school is the child's second home. A considerable portion of childhood is spent in the school. The necessity of keeping children well during this period is readily realized. As health director of the city schools of Albany for five years, I have had first hand information not only of local but also of state school health organizations. Each state has its own rules, regulations and laws. Some are more involved than others. Some are affiliated with the education department. Still others are associated with the state and local health bureaus. It is difficult to determine which is more efficient. As far as school health being directed by education authorities, as in New York State, is concerned, there is one thing that I particularly noted; that is, the complete dissociation of the various bureaus dealing with child health. For example, in the New York State department of education there are eight such bureaus. They are as follows: health teaching, physically handicapped, mentally handicapped (research), rehabilitation, physical education, medical inspection, medical examiners and dental examiners. The first five of these are supervised by teachers, the next two by physicians, and the last by a dentist. The confusion that not infrequently results may be realized when it is noted that at times the physical educator in charge of his department would be superior to the doctors and nurses in the medical inspection bureau. To a lesser extent health activities are supervised in other education bureaus.

My experience has shown me that every bureau is a separate and distinct entity. The bureau of medical inspection is most properly named in that the school physician seems to be employed particularly to inspect or examine the pupils. The other health duties mostly are relegated to the various bureaus mentioned.

The solution to the problem may not be too difficult. Two remedies I believe could be applied: 1. A physician should be in charge and directly responsible for the pupil's health in school, the same as it is in the home. 2. There should be an amalgamation and coordination of all education bureaus dealing in health. We know that we have those in our profession qualified in education as well as in medicine. There are two of our larger universities that have physicians as presidents. Many other medical men are prominent educators. One of these could capably direct and coordinate all the health bureaus so that there would be the greatest efficiency and at the same time unquestionably better economy. Simply to take the bureau of medical inspection from the department of education and place it in the

department of health would be to no avail, unless all the other health branches of education would be similarly transferred. This might present many difficulties. The plan mentioned would be more practical. This is in accord with the frequently expressed opinions of the American School Physicians Association, as mentioned in its journal.

In each state, departments of health and education, in conjunction with the state medical society, could undoubtedly evolve the most practical formula. The best results could thereby be obtained, whichever of Dean Smiley's plans would be acceptable, whether the school physician or, as he prefers, the private physician would have more contact with the pupil.

WILLIAM L. GOULD, M.D., Albany, N. Y.

HYPERSENSITIVITY TO ACETYL-SALICYLIC ACID

To the Editor:—In the February 6 issue of THE JOURNAL appears an article entitled "Hypersensitivity to Acetylsalicylic Acid (Aspirin)" in which the authors deprecate the use of aspirin in allergic conditions. They list (p. 446) ten conditions of an allergic nature which follow the ingestion of aspirin and make the statement "No more convincing argument against the use of acetylsalicylic acid as a remedy for asthma is needed except to point out . . . the cases of death resulting from its use by asthmatic patients." In THE JOURNAL, Nov. 21, 1936, page 1717, appears an article entitled "The Therapy of (Horse) Serum Reactions." Dr. Fantus recommends (p. 1719) the use of acetylsalicylic acid (a 0.3 Gm. capsule every two or four hours as required) as a remedy for the pruritus accompanying a serum reaction. I take it that the point of view of the two authors is rather diametrically opposite. It seems to me to be a point of some practical importance that some reconciliation be effected between these two divergent therapeutic thoughts.

ROY E. REED, M.D., New York.

[This letter was referred to Dr. Prickman, who replies:]

To the Editor:—In our paper "Hypersensitivity to Acetylsalicylic Acid (Aspirin)," Dr. Buchstein and I point out the serious reactions that occasionally occur following the ingestion of acetylsalicylic acid. We are aware that this remedy has been used by many allergic individuals without ill effects; one of our patients in fact estimated that he took 4,000 tablets (5 grains each) of acetylsalicylic acid a year for his asthma without encountering any trouble. However, it seemed to us very significant that sixty-one of the sixty-two individuals found sensitive to this drug had other allergic manifestations themselves or were from definitely allergic families. Nine additional patients hypersensitive to acetylsalicylic acid have been encountered since completing the study, and these also had other evidence of major allergy without exception. Since we found the reactions to acetylsalicylic acid very severe, at times even grave, and since we believe the incidence of sensitivity to acetylsalicylic acid to be greater than is ordinarily supposed, and since we have shown the persons who need to be especially cautious in using acetylsalicylic acid are those who have other allergy or come of allergic families, we believe that our conclusions are not unwarranted.

LOUIS E. PRICKMAN, M.D., Rochester, Minn.

[The letter was referred also to Dr. Fantus, who writes:]

To the Editor:—The fact is that dermatologists find acetylsalicylic acid in the form of 0.3 Gm. capsules their most efficient remedy against several varieties of pruritus, including that of urticaria, and this in spite of the fact that urticaria is one of the untoward effects of acetylsalicylic acid. Ill results from this treatment have not been brought to attention.

BERNARD FANTUS, M.D., Chicago.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

SNORING

To the Editor:—Will you be good enough to discuss the subject of snoring, especially as to etiology and treatment, preferably in "Queries and Minor Notes" or by direct correspondence? This subject must be of general interest since not a few patients have consulted me concerning it—but nowhere can I find any discussion of it.

H. J. HARRIS, M.D., Westport-on-Lake Champlain, N. Y.

ANSWER.—Snoring or unusual noises accompanying inspiration or expiration or both in deep sleep, in coma or in deep anesthesia involve several factors. The actual noises are made by intermittent passage of the air at regions of partial obstruction to the passage of the air. The factors that lead to such partial obstruction may be:

1. Partial obstruction of the glottis by approximation of the vocal cords owing to the extreme relaxation of the muscles governing the vocal cords.
2. The falling backward of the tongue, particularly when the person in deep coma or under anesthesia lies on his back.
3. Relaxation of the muscles governing the position of the soft palate, so that this structure falls against the roof of the pharynx or the hard palate. This would tend to interfere with the passage of the air through the nose in expiration if the person lies on his back.
4. Presence of mucus in the nasal passages.
5. Possible abnormal tonus both in the muscles of the pharynx as well as in the muscles of the soft palate.

The common explanation of snoring is that it is due to vibration of the relaxed soft palate. This explanation is probably inadequate, particularly as to the etiology of the snoring noises that may accompany expiration, because if the soft palate is completely relaxed and the person lies on his back it is more than likely to close the passage through the nose and not vibrate at all but merely force the air through the lips. If the lips are moderately closed, noises will be produced during the act of expiration.

One can voluntarily produce snoring noises during the waking state during deep inspiration with a partly closed glottis, intermittent passage of the air through the obstructed glottis producing the noise. One can similarly in a waking state produce snoring noises by voluntarily closing the pharynx from the nose by means of the soft palate and in expiration forcing the air through moderately tightened lips.

Snoring is an annoyance to other people rather than to the snorer. Rarely does snoring disturb the soundness of sleep of the snorer himself. It is not even classed as a functional pathologic condition. Snoring is less liable to occur if the person goes to sleep and stays asleep on either side or on the abdomen. A thorough clearing of the nasal passages before going to sleep also may aid.

KÜMMELL'S DISEASE OF SPINE

To the Editor:—Would you please give me information concerning Kümmell's disease or the so-called nucleus pulposus of the spine?

J. F. MALLOY, M.D., Mitchell, S. D.

ANSWER.—The inquirer evidently thinks that Kümmell's disease and nucleus lesions are synonymous: they are not. The reader may refer to the original book of Schmorl concerning the intervertebral disk and to the best English abstract, by Beadle.

The importance of the intervertebral disk is found in such conditions as injuries to the spine, kyphosis of senility, adolescent kyphosis, calcification or ossification of the disks and senile osteoporosis.

Keyes and Compere divide the pathologic lesions of the nucleus pulposus into four groups: (1) retropulsion or antipulsion of the nucleus pulposus, (2) lateral shift of the nucleus pulposus, (3) calcification of the nucleus pulposus, and (4) dehydration of the nucleus pulposus. Keller stated that the size and thickness of the intervertebral cartilages or disks are in close relationship to and developed in accordance with the amount and extent of mobility of the spine. The thoracic vertebrae, having limited motion, have the smallest disks, while the

cervical and the lumbar, with their free mobility, have the larger. The intervertebral disks act as shock absorbers, or buffers, and diminish the jarring of the vertebrae produced in walking, and also prevent the jarring of the steps taken from being transmitted to the head. The latter function is further assisted by the natural spinal curves. Any diminution of the size of the intervertebral cartilages will have an effect on the welfare of the body as a whole, through its irritating effect on the nervous system.

Although the intervertebral disks have been known for many years and were written about by Vesalius and Luschka in 1852, it remained for Schmorl in 1927 to disseminate information on which the clinical importance of these structures has been recognized.

Freedman states the intervertebral disk consists of the nucleus pulposus and the annulus fibrosus. The soft mass of the nucleus is usually eccentrically situated and is considered to be the remnant of the chorda tissue of the embryonic spine. The risks form approximately one fourth of the total length of the vertebral column and vary in vertical thickness in several regions, being thickest in the lumbar and thinnest in the upper thoracic region. The nucleus is highly compressible and elastic, the annulus relatively inelastic. The disks thus form delicate buffers between the vertebrae, absorbing shocks transmitted through the spine.

Schmorl thinks that a primary disease of the disk is possible only in young adults, as they possess a vascularized disk.

The disk consists of two parts, an envelop and a core. The former is made up of vertical plates of fibers, one within the other and grading in structure from ordinary fibrous tissue with crisscrossing strands on the outer part to white fibrocartilage on the inner part. The core is yellow and consists of highly elastic fibrocartilage, soft and pulpy in character, with some elastic fibers running through it. It is under great tension, so much so that when the envelop is slit horizontally this core bulges above the level of the surrounding tissues. The nucleus pulposus is a gelatinous substance under pressure and enclosed in the center of each intervertebral disk. The disk is composed of a peripheral fibrous ring called the annulus fibrosus, with a soft central substance. Inside the intervertebral disk, in the center of a compact fibrous ring and between two bony layers protected by a cartilaginous coating, is a gelatinous round mass, under pressure, called the nucleus. There is a direct connection between the epiphyseal plate and the disk. The annulus fibrosus is elastic and the nucleus pulposus is compressible.

Schmorl believed that the cartilage protects the vertebral tissue against the nucleus and the tissue of the disk against infection. Calvé and Galand believe that the nucleus acts as a bearing inserted between two adjacent bodies. The nucleus is important as an axis for the movements which under pressure provide for the elasticity of the disk; it transmits, absorbs and equalizes pressure. It is a soft gelatinous mass, irregularly ovoid, which is found under pressure in the center of each intervertebral disk. Compere called it a hydrodynamic ball bearing.

The clinical manifestations of Kümmell's disease were described in 1891 by Kümmell. It is called the Kümmell-Verneuil syndrome, post-traumatic spondylitis or vertebral collapse. The work of Leriche has helped to clarify the etiology and pathogenesis. He calls it traumatic malacia of the vertebral column.

This lesion is due to mild or severe injury to the spine, following which the patient usually passes through three clinical phases. The syndrome known by the names of Kümmell and Verneuil was studied by Bonnet in 1857. Schede also called attention to softening of the vertebrae secondary to trauma. Kümmell, however, was the first definitely to distinguish the three stages of the syndrome. In 1891 Kümmell described the wedge compression under the name of spondylitis traumatica. Great credit is due him because his work was done before the x-rays had been discovered. There are many unrecognized cases of Kümmell's disease.

The etiology is a moderate or severe trauma occurring in an otherwise normal back. The work of Kalisko and Schroll bears out the thought that Kümmell's disease is caused by minute traumas to osseous and ligamentous structures of the spine, the trauma causing chiefly cracks and small hemorrhages. Kümmell's article states that the disease does not always result from a compression fracture of the spinal segment but that in many instances trauma to the vertebral column without compression of the bodies is followed by rupture of the blood vessels and injury to the periosteum and atrophy of the spongiosa of the vertebral bodies followed by a gradual compression of the segments with a permanent kyphosis.

There are two explanations of the syndrome. According to one, the condition is the result of unrecognized fractures. According to the other, there is a secondary flattening of the vertebrae. It is well known that even severe vertebral fractures may be unrecognized and cause delayed symptoms. Roederer reports two cases of vertebral fractures that were at first not recognized; he states that undoubtedly a certain number of cases in which a diagnosis of Kümmell-Verneuil syndrome is made belong to this group. From observations made on the extremities it is known that osteoporosis may follow trauma. The resorption of bone may follow the prolonged hyperemia. The fact that in many cases presenting the syndrome a considerable portion of the spine is involved indicates that the initial lesion is not a fracture. Marie attributed the deformity to tearing of the anterior vertebral ligaments with subsequent retraction.

Blaine believes that the initial lesion is a minor degree of compression of a vertebral body, but careful x-ray examination of the spine made immediately after injury shows no fractures of the vertebra, which on later x-ray study is found to be decreased in height, indicating a partial collapse.

Leriche believes that Kümmell's disease is due to post-traumatic rarefaction and ossification due to hyperemia. He believes that the delay in the production of the rarefaction is due to the effects of hyperemia. This is brought about by the repeated internal trauma to an improperly balanced spinal column rather than by the external initial injury. Anything precipitating or increasing the process of vasodilatation such as an intercurrent infection, anything that impoverishes the bone and calcium, accelerates the evolution of the changes.

LATENT OR WASSERMANN FAST SYPHILIS

To the Editor:—After treating a man and his wife nine months intensively for syphilis with nearsphenamine and bismuth oxychloride I found that their serum test was little if any altered. They were:

	Man		Wife	
	Kahn	Wassermann-Kolmer	Kahn	Wassermann-Kolmer
Feb. 11, 1936.....	1 plus	4 plus	4 plus	4 plus
June 13, 1936.....	2 plus	4 plus	4 plus	4 plus
Dec. 18, 1936.....			3 plus	4 plus

They were not treated for syphilis until February 1936. The man had apparently contracted the disease four and one-half years before that date and the wife about (this is surmise) three and one-half years before that same date (February 1936). Can you tell me what prognosis as to cure there is? What amount of treatment should be taken if the attempt to eradicate the disease is given up? Is sexual intercourse harmful? An authoritative opinion on these points would be appreciated. The general health of the patients is fairly good. There are no clinical signs or symptoms of syphilis.

F. F. CARR-HARRIS, M.D., Timagami, Ontario.

ANSWER.—This inquiry emphasizes a misconception that is prevalent regarding the treatment of syphilis. The Wassermann reaction remains positive because of the patient's disease and not because of the treatment, even though it is given in insufficient amounts. In other words, in order to determine why the Wassermann and flocculation tests have remained positive in this man and woman it will be necessary to determine the status of the disease in each patient. This will necessitate a spinal fluid examination and a cardiovascular examination, as well as search for evidence of other types of visceral syphilis. If these examinations are completely negative it is probable that the diagnosis of latent syphilis is warranted in both patients. If, however, one or more of these examinations are positive, it is then possible to account for the serologic resistance.

If the diagnosis of latent syphilis is warranted, too much concern should not be manifested over the positive blood tests. If the nine months of treatment included twenty or more injections of arsphenamine and twice as many of a bismuth compound, this is the minimum amount that should be given and ten more injections of arsphenamine and twenty of a bismuth compound might well be administered. On the other hand, if more than the minimum has been given it would be advisable to give two courses of bismuth, fifteen injections each, a year for the next two years; reexaminations every six months for evidence of cardiovascular or visceral syphilis should be carried out. The majority of patients with latent syphilis observed for a period of ten years have become serologically negative. The important point is to make sure that the patients have latent syphilis before placing them on their own defensive mechanism.

The hazard in sexual intercourse to this couple lies in the possibility of pregnancy. If the woman has passed the child-bearing age there is no contraindication to coitus, as they both have the disease. In view of the positive Kolmer and Kahn

tests the woman must avoid pregnancy, and if she is averse to the use of contraceptives and has no pelvic disease that will prevent pregnancy, the risk of having a syphilitic child must be fully explained to the couple.

INFECTION FROM ANESTHETIC FACE MASK

To the Editor:—I am writing regarding the possibility of infection from gas and ether masks such as are used on ordinary commercial machines. As you know, these face pieces are made from celluloid or similar material and are connected to a rubber rebreathing bag by 3 to 4 feet of tubing, the latter having some eighty or ninety deep corrugations. Most places sterilize these by washing them in soap and water. For many years I have used Gwathmey's face mask, which is made of metal and connected to a tank by a small tube. The face mask and rebreathing bag can be sterilized by boiling.

CHARLES N. SPRATT, M.D., Minneapolis.

ANSWER.—The possibility of infection from masks such as are used on ordinary commercial gas and ether machines is relatively remote if the ordinary precautions are exercised. R. C. Coburn (Safety and Science in Nitrous Oxide Administration, *M. Rec.* 82:798 [Nov.] 1912), in writing on administration of nitrous oxide, advocated "sterilization of all parts contaminated by breathing." Ordinarily, the instructions issued by the manufacturer of equipment to the user indicate the desirability of washing the mask and tubing with soap suds and hot water. It should be emphasized that it is highly desirable to keep on hand a sufficient amount of equipment so that, when one is suspicious that an unusual infection is present, the metal parts involved can be autoclaved, the rubber parts can be boiled, and the celluloid parts or those that cannot be boiled can be immersed in an antiseptic solution for a sufficient time to insure their sterilization. Solutions used are made with mercury bichloride or saponated solution of cresol, and some anesthetists use alcohol in proper dilutions or formaldehyde. Solutions should be well rinsed off, for rubber picks up cresol readily, as has been shown by R. P. Herwick and D. N. Treweek in their study of burns from an anesthesia mask sterilized in saponated solution of cresol (Burns from Anesthesia Mask Sterilized in Compound Solution of Cresol, *THE JOURNAL*, Feb. 11, 1933, p. 407). Caution must be exercised when this solution is used for sterilization of rubber parts that make contact with the skin.

Most modern gas machines are equipped with canisters for soda lime, which is an absorber for the carbon dioxide that is eliminated in the mixture. R. M. Waters wrote as follows (Carbon Dioxide Absorption from Anesthetic Mixtures, *California & West. Med.* 35:342 [Nov.] 1931): "It has been suggested that the danger of cross infections was enhanced [by the canister of soda lime]. The mask is removed from the canister after each anesthesia and thoroughly washed with soap suds and hot water, rinsed in hot water and dried, unless a particularly dangerous case from the standpoint of infection has been handled, when further sterilizing procedures are instituted. The canister containing soda lime granules may be autoclaved with surgical dressings if necessary. The breathing bag may be washed in alcohol, boiled or otherwise sterilized. The possibility, however, of bacterial contamination was investigated by Dr. W. D. Stovall, director of the Wisconsin State Laboratory of Hygiene and visiting bacteriologist at the Wisconsin General Hospital. His reply follows: 'Complying with your request to carry out some bacteriological examinations to determine the probability of your anesthesia apparatus acting as an agent for conveying bacteria from one person to another, I have performed two sets of experiments. First, I poured a culture of staphylococcus into the canister containing soda lime. I then drew air, which was first washed through several washings of sterile distilled water, through the soda lime in the canister and through beef infusion glucose broth. This experiment I allowed to run two hours and at the end of that time the cultures were placed in the incubator for a period of a week. In no case did the culture show a growth of any kind. The other experiment was made by blowing air into a bottle containing a suspension of *Bacillus prodigiosus*. The air was blown through this suspension of bacteria so that it agitated it and made a fine spray in the bottle. Through a small glass tube which reached just through the cork of this bottle, I drew air by a process of suction through the soda lime of the canister and then through glucose beef infusion broth. These cultures were also incubated for one week. None of them showed any growth. While this is a limited number of experiments, I consider that the apparatus was submitted to a very severe test and I believe that, if the bacteria do not find their way through the canister into the media by these experiments, there is certainly no possibility of bacteria being transferred from one patient to another by con-

tamination of the lime in the canister.' In order to completely cover this situation, Guedel has made it a practice to place mask, canister and bag in a muslin container, autoclaving the container and contents after each anesthesia. From the standpoint of the 'cleanliness appeal' to the patient, we believe this a good practice, although entirely unnecessary for the complete avoidance of cross infections."

It is probable that, if these commonly applied principles of cleanliness and asepsis are employed, the ordinary patient can be safely anesthetized following the previous use of the equipment for anesthetization of another ordinary patient. Obviously, however, it would be best that a patient who is known to have a contagious respiratory infection should be the last one listed for operation on a given day. If this is not possible, following the use of the equipment for anesthetization of such an individual the metal, rubber and celluloid parts should be sterilized in the manner recommended in the opening paragraph. The soda lime in the canister should be discarded after use in each suggestive case.

A report of an address on ether pneumonia, given by J. M. Anders (Ether Pneumonia, *Brit. M. J.* 2:6 (July 9, epitome of current medical literature, 1898) reads in part as follows: "The micro-organisms giving rise to the pneumonia were probably not usually obtained from the mask or inhaler used, but it was likely that partly dried secretions were loosened by the moisture in consequence of the increased secretion of the mucosa caused by the irritating effects of the ether, and that they were thus drawn into the lungs. In all the cases that had come under his own observation there was bronchitis, coryza or some other inflammatory condition of the respiratory tract before the administration of the anesthetic. Any such predisposing causes should, if possible, be removed first."

In certain special fields, special methods and special equipment may be necessary, and the equipment should be designed with the idea that it can be sterilized.

Contamination of apparatus, even though it is not used, is a remote possibility, but even this possibility can be minimized by care and proper covering of the apparatus and by its being placed in a room as clean as an operating room should be.

ACID ASH FOODS AND SALTY TASTE IN MOUTH

To the Editor:—A woman, aged 53, who has been considerably overweight for a number of years, is now reduced but not to a normal weight. She complains of a salty taste in her mouth, which is aggravated by postnasal dripping and is worse when she is nervous. I told her I thought it was due to a reduced alkalinity, because they are a family who eat a lot of acid forming foods: steaks, meats, white bread and butter.

M.D., Georgia.

ANSWER.—The acid forming and base forming qualities of foods have received considerable attention from some clinicians and a great deal of incoherent discussion by laymen.

In general, one should take at least enough alkaline ash to balance or neutralize the effect of the acid ash foods. The best health of the tissues depends on maintaining a slight preponderance of bases over acids in the body.

A general classification is given to show what foods in general yield the neutral, acid and alkaline ash:

Neutral Ash	Acid Ash	Alkaline Ash
Butter	Egg	Milk
Cream	Meat, fish and poultry	Nuts
Oil	Oyster	Fruits (except cranberries, plums, prunes and rhubarb)
Lard	Bread of all kinds	Vegetables (especially legumes and white potatoes)
Sugar	Cereals	
Cornstarch	Pastries	
Tapioca	Puddings	

Among the many ideas, fads and fancies about diet encountered by the physician is the "acid fad" in diet. Many patients worry and attribute their ills to what they believe to be acidosis resulting from the eating of acid foods. They feel that acid stomach, water brash and heartburn are all due to too much acid in the system from eating acid foods. They therefore eliminate many articles of food from their diet for fear they will produce acid in the body and by so doing they are apt to secure an inadequate diet.

There is a great variation in gastric acid secretion and often the secretions bear little relation to the average diet. After organic disease is excluded, the physician should realize that the acid secretions may be due to neurotic tendencies or to chronic nervous exhaustion and fatigue. Acid stomach, water brash and heartburn are not due to too much acid in the system from eating acid foods. The patient must be taught that taste does not tell whether a food is acid or alkaline. For example, eggs and meat form acid in the body, while orange, grapefruit and tomato are alkaline formers. If one includes in

the diet a generous amount of vegetables, fruits and milk, one is sure to have a well balanced diet.

In general a heavily coated tongue will have impaired taste function, the taste bulbs being covered by the deposit. Swelling of the mucous membrane of the nose, with consequent obstruction, brings on an early perversion or absence of the sense of taste and smell. Irritating condiments also impair the sense of taste. A large group of taste reflex perversions are found in vagotonic persons, chiefly of gastric origin. Psychogenic taste modifications such as metallic tastes are frequently found in neuroses.

In view of the fact that the patient finds that her salty taste is aggravated by postnasal dripping and is worse when she is nervous, the nervous reaction that stimulates the postnasal dripping is more likely responsible rather than any relation of acid ash or alkaline ash foods.

PAIN AND CIRCULATORY DISTURBANCE IN FOOT

To the Editor:—A woman, aged 58, for the past two years has been having severe pains in one foot, the pains beginning in the great toe and spreading over the rest of the toes. The foot is cold and the pains last from six to twenty-four hours, being relieved only by hypodermic injections of morphine and atropine sulfate. Glyceryl trinitrate, contrast baths, barbitol, acetylsalicylic acid and other preparations recommended for intermittent claudication give no relief. The basal metabolism, blood count, urinalysis and the heart and lungs are normal, the Wassermann reaction is negative, x-ray examination of the leg and foot shows no excessive calcification of the arteries, and the blood pressure is 150 systolic, 90 diastolic. She is wearing an orthopedic shoe. The attacks are getting more frequent and more severe and I am desirous of preventing these attacks. She is a seamstress at a hospital and runs an electric sewing machine all day. She is overweight but by dieting I have reduced her 20 pounds (9 Kg.) in three months. Please omit name.

M.D., New Jersey.

ANSWER.—The information contained in the inquiry is too inadequate to allow one to make a diagnosis. Desirable information is a more detailed history of the disease, a record of pulsations in the arteries of the legs, the effect of elevation and dependence on the color of the foot, and the presence or absence of sensory changes and changes in reflexes. Diabetes should be excluded by determination of the sugar in the blood and by studies of dextrose tolerance. It is quite apparent that the patient does not have intermittent claudication, since this condition is characterized by distress brought on by exercise and relieved by rest; however, she may have ischemic neuritis secondary to diminished blood supply resulting from arteriosclerosis obliterans. Such a diagnosis must be based on objective evidence of diminished blood supply, such as absence of pulsations in the dorsalis pedis, posterior tibial and popliteal arteries, abnormal pallor with elevation of the foot, abnormal rubor with dependence of it, and lowered temperature of the skin. A complete neurologic examination is advisable. Tabes dorsalis is to be considered. Provided no primary disease amenable to treatment to which the distress could be secondary is detectable, section, injection or crushing of the peripheral nerves (*Ann. Surg.* 98:55 [July] 1933) or the intraspinal injection of alcohol (Greenhill, J. P., and Schmitz, H. E.: Intraspinal [Subarachnoid] Injection of Alcohol, *THE JOURNAL*, Aug. 10, 1935, p. 406), or roentgen treatment of the lumbosacral spine should be considered. Occasionally, such episodes of pain are characteristic of erythromelalgia (*Ann. J. M. Sc.* 183:468 [April] 1932), which is frequently associated with polycythemia.

DERMATITIS FROM HOSIERY DYES

To the Editor:—What is the latest treatment or the most common treatment for acute and chronic dermatitis caused by dye powder (used to dye hosiery)? Also that caused by silk and wool? I have had good results with ultraviolet when the patient will stay home for two or three weeks but some are unable to give up their work, owing to financial difficulties. What would be your procedure in these cases?

M.D., Pennsylvania.

ANSWER.—The treatment of external irritant dermatitis follows the principles of the treatment of dermatoses in general. However, the first essential is to remove the causal agent that is exciting the cutaneous reaction. The activities and environment of the patient in addition to his work may reveal contributory sources of irritation. In the event that it is impossible to prevent further contact with an irritant in the patient's work, the patient must be protected. Those who are mildly affected can continue work by protection of the parts by long sleeves and gloves and a protective ointment. Desensitization as a means of treatment has not met with success in the case of chemical (dye powder) dermatitis. Desensitization to silk and to wool by subcutaneous injections can be attempted. Those cases exhibiting an acute dermatitis are best removed from their work and the source of irritation.

The local treatment of the dermatitis during the acute stage should consist of wet dressings of saturated solution of boric acid, or solution of aluminum subacetate, 1 part diluted with from 10 to 16 parts of water. Calamine lotion compresses, to which phenol may be added if there is much itching, are also effective. The use of boric acid ointment or 2 per cent ichthammol (ichthylol) in zinc oxide ointment may be applied at night. In the chronic cases one should rule out any general factors that may contribute to the chronicity, and the use of a 3 to 6 per cent crude coal tar ointment in zinc paste or a 3 to 10 per cent oil of cade ointment, starting with the milder strengths and cautiously increasing the strength, is effective. Fractional x-ray treatment, 75 roentgens once a week in competent hands for from six to eight doses, is a valuable adjunct to treatment.

PROPHYLAXIS OF RABIES IN DOGS

To the Editor:—At a local medical society meeting recently there was considerable discussion over the single prophylactic injection of dogs for rabies. Can a family feel secure their pet dog will be immune from rabies after the single injection of antirabies serum as a prophylactic? Does it take several preventive doses to protect satisfactorily against development of hydrophobia in the dog? Pardon the question about dogs, but dogs and people are usual inhabitants of the same house; in fact, I have one myself; and children playing with these pets may easily contract the disease innocently from their own pet if the prophylactic doses we have been accustomed to use from the manufacturers are not really protective. A few dogs have been reported as developing rabies following the prophylactic injection of antirabies serum, which was the reason for the claim being fostered. In such cases is the reason likely that the rabies infection was massive or close to the brain (the entrance of the virus) or insufficient time for immunity had not elapsed between prophylactic administration and the rabies bite to develop the necessary immunity?

E. H. COACHMAN, M.D., Muskogee, Okla.

ANSWER:—Robert Olesen (*Pub. Health Rep.* 50: 1087 [Aug. 16] 1935) reviewed the available data on the effectiveness of vaccination against canine rabies. He states with reference to canine antirabic vaccination: "Unfortunately evidence concerning the value of available vaccines is conflicting, indecisive and unsatisfactory. The evidence seems to indicate strongly that vaccination against rabies is in the experimental stage and that, despite the claims of a few enthusiastic advocates, reliance should not at present be placed upon this measure."

However, it is the consensus that, when antirabic vaccination in dogs is successful, the resulting immunity has a duration of about one year, after which vaccination should be repeated.

Immunity that is the result of antirabic vaccination requires time for its development. In man it is reported as appearing about two weeks following the Pasteur treatment. It is reasonable to believe, therefore, that during this period of the development of immunity the vaccinated dog may still be susceptible to rabies and may contract the disease if exposed at this time to the virus in massive doses or by head bites.

SUDDEN DEATH DURING MENSTRUATION

To the Editor:—A white woman, aged 24, apparently in good health, helped her husband pile some brush, and sawed wood all day. She had been menstruating for three days previously. After doing her usual evening work she sat down and attempted to lift her only child, aged 2½ years, but suddenly dropped over dead. There is no history of hypertension, rheumatic fever, syphilis or other symptoms of heart disease. I was called to see the patient, arriving at the home about twenty minutes after death. The body showed nothing in particular that would explain the sudden death. No autopsy was done. Would you kindly render your opinion as to the cause of death? I had never seen the patient previously and only a brief history was obtained from the sorrow-stricken family. Do you think the fact that the patient was menstruating is of any significance in this case?

M.D., North Carolina.

ANSWER:—It is not at all likely that menstruation was of any significance in the death of the patient. The cause of a sudden death like this is to be found first and most probably in the heart.

APPENDIX AND PERISTALSIS OF COLON

To the Editor:—Please inform me if the appendix is the initiator of peristalsis of the colon. What are the latest theories as to what causes the peristalsis in the colon?

J. MARSH FRÈRE, M.D., Chattanooga, Tenn.

ANSWER:—There is at present no evidence that the appendix in any way governs the movements of the colon. On Alvarez's "gradient theory" of intestinal motility one might look for such motor influence from the appendix, but removal of the appendix in man and other animals reveals no such influence.

The colon motility, like the rest of the intestine, is influenced by local and by extrinsic factors. Among the latter are the extrinsic nerves to the colonic musculature and the hypogastric and the sacral autonomies. It is probably mainly through these

nerves that spastic states and the so-called gastrocolonic reflex (increased colonic motility and tendency to defecation after eating a full meal) take place. The local factors are distention of the colon by its content (indigestible parts of the food, gas, enemas) and irritation of nerve endings of the mucosa. The latter appears to act both through the extrinsic nerves of the colon and through Auerbach's plexus in the wall of the colon.

FIRST USE OF TERM "LA GRIPPE"

To the Editor:—In the current novel "Gone with the Wind" I find the term "la grippe" used in describing an ailment. The time portrayed in the book is Civil War time, 1860-1865. It is my impression that the term "la grippe" was not used in United States medical circles until in the early 1890's, when an influx of it swept over the United States, supposedly imported from France. Will you kindly give me your ideas on this subject? We had in the United States what was once known as "Tyler's grip," but I believe this was before the Civil War.

W. G. MCGLUMPHY, D.D.S., Moundsville, W. Va.

ANSWER:—In France "la grippe" has been used since the epidemic of 1743 (Townsend, J. G.: A Review of the Literature on Influenza and the Common Cold, supplement 48 to *Public Health Reports*, 1924). The term was used in the United States even before the Civil War, as shown by the following references:

McCall, A.: Some Account of the Epidemic "Grippe," *Boston M. & S. J.* 31:254, 1844-1845.

Stewart, E. C.: An Account of the Epidemic Influenza Prevailing at Paris, Known There Under the Name of La Grippe, *M. Examiner* (Philadelphia) 1:353, 1842.

ALLERGY TO HAM

To the Editor:—Recently I have had several cases of allergy which have been traced to eating ham. I was wondering whether you could tell me how the hams are cured. Is a chemical used in curing the ham? If so, what is the chemical?

ROBERT N. HEDGES, M.D., Chicago.

ANSWER:—The substances used in the curing of ham are salt, sodium nitrate, sodium nitrite, sugar, and wood smoke. Only special hams, easily recognizable by the color and specific odor, as the Italian ham, have spices. These are various peppers and occasionally paprika. None of the substances used in the curing of ordinary ham have been found to be the cause of any allergic symptoms, although Duke has reported a case of asthma due to wood smoke. This, however, could not possibly apply to the concentrations of smoke present in cured ham.

USE OF PHENOL AND GLYCERIN IN OTITIS MEDIA

To the Editor:—What is considered the best management of the early stage of acute otitis media prior to suppuration? Otologists seem to object to the local use of phenol and glycerin, glycerin, or hot irrigations to the canal. What nasal treatment is advised

M.D., New York.

ANSWER:—Otologists do not object to the local use of phenol and glycerin or plain glycerin in the early stages of acute otitis media. Intended chiefly for their anesthetic and perhaps antiseptic qualities or to deplete the middle ear, these agents may be used in the first twenty-four to forty-eight hours of an acute otitis; if the symptoms are not improved by the end of that time then the logical thing to do is a paracentesis of the drum membrane. Closing one's eyes to symptoms and placing undue reliance on the efficacy of local anesthetics is not good otologic practice. The prolonged use of phenol furthermore leads to a desquamation of the epithelium of the external auditory canal and coats the drum membrane with a white debris. Landmarks thereby become so lost that decision as to future therapy becomes difficult.

BURNS OF EYE

To the Editor:—What is the best acid substance for neutralizing an alkali burn of the eye? The best alkali for neutralizing an alkali burn of the eye?

M.D., Massachusetts.

ANSWER:—The best substance for primary use in either an alkali or acid burn of the eye is ordinary water in large quantities. The purpose is to dilute the damaging chemical as much as possible and to flush all excess from the conjunctival sac. As a rule, when an eye is burned with a chemical substance no neutralizing solution is at hand for immediate use. But if a neutralizer were available it would not be of much more use than ordinary tap water, for any acid or alkali sufficiently concentrated to neutralize an alkali or acid substance in the conjunctival sac would do as much damage as the original injuring agent. The damage is done within a few seconds and later neutralizing agents are of but little value.

Dr. Robert Frère Library

A. J. A. Medical College

34

However, in the case of acid burns, a 3 to 5 per cent solution of sodium bicarbonate is as efficacious as anything else, while in the case of an alkali burn a 4 per cent solution of boric acid suffices. The quantity and rapidity of use is of far greater importance than the quality.

KAHN TEST OF CORD BLOOD

To the Editor:—Kindly inform whether or not in your opinion the Kahn test using cord blood is satisfactory. I shall appreciate a reply, for I am doing the Kahn test as a routine in all obstetric cases, using cord blood. If it is not the correct procedure, I should like to make a change.

M. G. SHARP, Ottawa, Ill.

ANSWER.—The question of the dependability of the Kahn test carried out with cord blood has been discussed in these columns previously (*THE JOURNAL*, March 25, 1933, p. 991). Judged from published reports, the Kahn test is as reliable with cord blood as with non-cord blood. The belief that tests for syphilis do not give dependable results with cord blood is based on the fact that serum from such blood shows some tendency toward nonspecific fixation of complement (anticomplementary action) in complement fixation tests. But the Kahn test does not employ complement in its set up and is apparently not influenced by anticomplementary properties of serum.

PARALYSIS AGITANS

To the Editor:—Will you please advise me what the most recent opinion is as to the choice between atropine, stramonium and scopolamine in the treatment of cases of paralysis agitans. I have a patient who seems to be rather sensitive to atropine, although it does prove rather effective in controlling the tremors.

JOHN THOMAS BOWEN, M.D., Clearwater, Fla.

ANSWER.—All three of these drugs have been used with some success in the treatment of paralysis agitans and it may be that one of them might agree better with a certain patient than another one, so that treatment with the different drugs in succession is decidedly desirable. It is the side-effects, which are similar in all of these drugs, that limit their practical utility; but they may, in a certain case, appear later with one of them rather than with the other.

TERPIN HYDRATE IN ELIXIR

To the Editor:—In *THE JOURNAL*, Sept. 14, 1935, page 879, Dr. Fantus gives a prescription as follows:

R Terpin Hydrate 5.0 Gm.
Iso-alcoholic elixir 60.0 cc.

M. Label: One teaspoonful in water every three hours.

My druggist reports that he cannot dissolve the terpin hydrate in this amount of elixir. He seems to be correct when I note that the proportions are 1:12 and that terpin hydrate is soluble in 95 per cent alcohol only in the proportions 1:13. Is this prescription in error or does my druggist have a poor elixir preparation? Please omit name.

M.D., Ohio.

ANSWER.—High-alcoholic elixir (N. F.) will dissolve the indicated quantity of terpin hydrate on prolonged shaking or on standing over night.

PRISM EXERCISING OF EYE FOR SQUINT

To the Editor:—An opinion was expressed to me by a physician that there was some danger or possible damage that could result from exercising the eyes with prisms, as in squint cases. What is known concerning such danger?

M.D., North Carolina.

ANSWER.—If the muscle imbalance is properly diagnosed and the prism exercises are properly done and the condition is properly checked at adequate intervals, there is no possibility of danger or damage.

PUBERTY MASTITIS

To the Editor:—I wish to inquire as to the significance, in a boy aged 13½ years, of bilateral indurated and slightly tender disks underlying the nipples and areolae. My experience with boys of this age is limited. Were this child a girl I should be sure that this was a normal manifestation of puberal development, and I think that it probably is so in this case also. Is this condition common in boys? M.D., California.

ANSWER.—The so-called puberty mastitis or mastitis adolescentum occurs in boys as well as in girls. It is probably more common in boys than is generally assumed, and it may become so marked as to constitute a true fibrous tumor. It may involve one or both breasts. It regresses spontaneously in most cases after several weeks or months. The term puberty mastitis is somewhat misleading, since in typical cases the process is not inflammatory.

POSTMORTEM LIVIDITY

To the Editor:—Will you please give me some authentic information on the time the lividity of the skin and subcutaneous tissue lasts after death from sudden and complete obstruction of the upper air passages. What is the cause of the lividity and the cause of death in such a case? I understand there has been some experimental work done on this subject in recent years.

ALEXANDER GALBRAITH, M.D., Oakland, Calif.

ANSWER.—The lividity would persist until obscured by decomposition and other postmortem changes. The lividity is due to venous obstruction from the interference with the respiration, which in turn is the cause of death in such cases. This is not to be confused with ordinary postmortem lividity.

BIOLOGIC PREPARATIONS IN FURUNCULOSIS

To the Editor:—May I have your comments on the relative merits of stock vaccines, autogenous vaccine and staphylococcus toxoid in the treatment and prevention of furunculosis?

M.D., Massachusetts.

ANSWER.—A potent, well prepared autogenous vaccine is more effective in the treatment of furunculosis than either toxoid or a stock vaccine. Staphylococcus toxoid exhibits a slightly higher degree of effectivity in selected cases than stock vaccine.

INTRAVENOUS USE OF CALCIUM COMPOUNDS IN DIGITALIZED PATIENT CONTRAINDICATED

To the Editor:—Is calcium, intravenously administered, contraindicated in a patient who is partially or wholly digitalized? Please omit name.

M.D., Texas.

ANSWER.—There is a decided danger from intravenous injection of calcium salts in a digitalized patient. Several deaths are on record from this cause.

GOLDSTEIN'S HEMATEMESIS, GASTRORRHAGIA AND GASTROSTAXIS

To the Editor:—Gastric bleeding (gastrorrhagia) discussed in *THE JOURNAL*, Dec. 19, 1936, page 2072, suggests that this condition deserves a special name and states that no description of it appears to have been published. The use of moccasin snake venom injections also is mentioned as having been used by Watkins of the Mayo Clinic with excellent results.

Reports and descriptions of this gastric hemorrhagic condition have been reported, with "special names," such as "gastrostaxis" (White, W. H.: *Lancet* 1:416, 1912), "telangiectatic dysplasia of the stomach with hemorrhages" or "Goldstein's Hematemesis" (*Arch. Int. Med.* 48:836-865 [Nov., part 11] 1931; *Arch. Dermat. & Syph.* 26:282-308 [Aug.] 1932; *Brit. M. J.* 1:1275 [June 20] 1936; L. N. Boston [1930]; Ersner [1931]; Schoen [1930]; Ullmann [1896], and others).

I suggest that these cases are due to dysplasia and telangiectatic bleeding when no other evidence is found, such as abdominal Hodgkin's disease, hemorrhagic blood dyscrasias, leukemias, severe anemias, uremic states, malignancy, polyposis, hepatic cirrhosis or chemical poisoning, vicarious menstruation (substitutional extragenital bleeding and supplementary menses), and gastric allergy. Russell viper venom in solution has been used by mouth for gastric bleeding.

HYMAN I. GOLDSTEIN, M.D., Camden, N. J.

BLOOD-TINGED SEMEN

To the Editor:—In *Queries and Minor Notes* in *THE JOURNAL*, January 30, page 416, is a question concerning blood-tinged semen. Having seen a similar case, I would suggest a possible explanation. The patient referred to was a married farmer, aged 51, who first noticed the appearance of bloody semen in 1934; it varied from reddish brown to light red. Microscopic and chemical examination confirmed the diagnosis of bloody semen. No pathologic condition was found on endoscopic examination. The condition lessened and stopped within nine months. He remains well. Treatment consisted of weekly prostatic massage and instillations of silver nitrate and interdiction of his habit of coitus interruptus, which he had practiced throughout his entire married life. There is reason to believe that withdrawal was the prime cause of the condition, resulting in chronic congestion in the sex organs, probably localized in the vesicles. There seems no reason why congestion of the posterior urethra and prostate could not occur on this basis.

HAROLD J. HARRIS, M.D., New York.

OTITIS MEDIA AND EPILEPSY

To the Editor:—In *THE JOURNAL*, January 30, page 414, there is a question from a physician concerning a patient who has epilepsy with a chronic otitis media. In answer the statement is made that the otitis described is not the cause of the convulsions. There is considerable doubt in my mind whether the question can be answered with such a categorical negative. In the Neurological Unit of the Boston City Hospital we have had three patients with epilepsy and chronic otitis in whom the attacks have ceased following radical operation on the mastoid. While I am aware this is only a post hoc argument, I think it does create a presumption.

TRACY J. PUTNAM, M.D., Boston.

Leadership in Medical Education

DR. RAY LYMAN WILBUR, Stanford University, Calif.: This article appeared in full in *THE JOURNAL*, March 6, page 771.

The Regulation of the Professions in the Public Interest

WILLIAM E. WICKENDEN, B.S., Cleveland: The protection of public welfare in matters of professional service involves at least three major considerations—keeping incompetent or unscrupulous men out, getting a sufficient quota of men of high character and ability in, and maintaining the economic and social conditions of practice essential to an adequate and disinterested service of the public. By origin and tradition, professions are self-regulating bodies. In general, each profession has built up its own status, determined its own conditions of admission, established its own code of ethics, and fixed its own system of compensation for services. The public has been tolerant toward professional autonomy until its own interests have become endangered. When public regulation has been imposed, the intent has been not to take the control of a profession out of the hands of its members but merely to establish such rules of control as are deemed necessary to public interest.

The occasion for such regulation and its extent differ significantly as one passes from those professions which deal with personal emergencies to those which touch social interest mainly in the area of corporate activities. A personal emergency of health or safety, or a problem of mental or psychic adjustment calls for a type of knowledge too esoteric for the layman to judge competently for himself. These fields have always been beset by quacks, charlatans and miracle workers, and even intelligent people when faced by extreme emergencies show an almost uncontrollable tendency to throw sober science to the winds and grasp at fabulous nostrums. The average man, facing the power of the law, is usually reduced to an abject helplessness which leaves him open to shameless extortion.

To leave the public exposed to quackery and exploitation under these circumstances would violate every consideration of humanity and public interest. In commercial transactions the buyer and the seller are presumed to meet on equal terms, with the buyer free to decline the terms offered. The man with acute appendicitis does not enjoy these advantages. The least the public can do for the distressed individual is to guarantee that whatever professional servant he may engage has at least certain minimum standards of training, experience and character, and to impose on the practitioner that degree of accountability for his conduct and performance which public safety demands.

Where the interests and responsibilities of one profession run closely parallel to or overlap those of another, some delimitation of fields by statute has often been found to be necessary. This usually takes the form of restrictions on the right to sign and file plans for approval by the authorities charged with the supervision of building operations in the interest of public safety. What regulation through licensure and statutory definition of powers in the interest of public safety accomplishes directly is simply an imposition on the profession of minimum standards of admission, in terms of training, experience and social accountability. The immediate aim is to exclude incompetents, pretenders and crooks. Indirectly, licensure operates

to regulate competition within the profession and to invest it with a greater or less degree of prestige in the public mind.

The restriction of admissions to certain professions is clearly in the public interest, while in others it is much more questionable. This point may be exemplified by contrasts in status and function between the physician and the engineer. Medicine, as every one knows, is one of the group of professions which serve individuals in personal emergencies. The incidence of these emergencies in a population living on a given social level is well known and determines the number of persons a single physician can serve effectively. Inevitable inequalities in distribution and service must be allowed for, but an optimum quota or ratio of physicians to population is easy to establish. An increase of physicians beyond this quota does not insure superior service nor does it contribute to medical progress; on the contrary, it merely multiplies temptations to exploit human ignorance and frailty on the plea that surplus practitioners must live, somehow. Competition may be the life of trade but it is likely to be the death of good medical care. Furthermore, medicine is a sharply bounded occupation from which few men are called by choice or circumstance to other careers; nor are there easy gradations of authority to keep a career open to the self trained. Every French private, according to Napoleon, carried a marshal's baton in his knapsack, but no hospital orderly is permitted the illusion that he may somehow rise to the rank of chief surgeon.

Engineers seldom serve individuals. They serve society through its corporate agencies and in its constructive enterprises. No statistician can state the incidence of these constructive needs; their number is not inherently limited, nor does engineering progress tend to restrict or eliminate them as medical progress aims to banish disease. Rather, all engineering progress tends to widen the domain of engineering. No one can set an optimum quota of engineers for a given population, nor is it clear that a sharp restriction of their numbers is necessary for public welfare and safety. To have fewer engineers does not necessarily imply better engineers, so long as their work lies principally in areas of competitive enterprise. Technical progress in engineering apparently is little affected by overcrowding except as the horse sense of one generation is unable to compete successfully with the science of the next. To create and protect a monopoly for the horse sense generation might have been in their personal interest but not in the interest of scientific advance. The profession of medicine is by law and tradition a caste; sharp, closed boundaries separate it from nearly all other groups that touch on its functions such as pharmacists, laboratory technicians, nurses and opticians. The profession of engineering is not a caste but a vaguely bounded nucleus within a large body of technical workers and officers of industry. The gradations of function between highly technical specialists at one extreme and almost pure executives at the other are imperceptible. Constant interchange between these functions within the larger group are going on. Close these free paths of interchange between technical, executive, commercial and producing groups, and the engineering profession would quickly sterilize itself.

A wide range of professional patterns exists, and too much regimentation under the law, aiming to impose a common pattern, would be stultifying in its effect. Licensure is effective in setting minimum qualifications for admission only, and in strengthening the police powers which may be invoked in cases of malfeasance. In itself it offers no positive assurance that men of high caliber and devoted spirit will be drawn into any field of professional service. In itself it invests a profession with only a modicum of public prestige and esteem. The state of New York issues professional licenses in the fields of medicine, podiatry, dentistry, pharmacy, veterinary medicine, nursing, accountancy, optometry, shorthand reporting, architecture, engineering and public school teaching—a range of professions varying so widely in public prestige, as to make it clear that licensure, *ipso facto*, is in no sense a key to esteem.

Public regulation has done little to lessen or to alter the inner obligations of our professional groups. We are still responsible for our standards of education and of personnel selection. These standards operate at the doors of our professional schools even more significantly than in the examining rooms of the licensing boards. Our part is to get the right

men in; the board can merely keep the wrong man out. As professions, we are still responsible for the advancement of the knowledge and skill we have received as a priceless patrimony from our forebears. No legal status can possibly affect our groups in public esteem and prestige as much as do our contributions to knowledge and public well being. The cultivation of professional spirit, the nurture of the ideals of disinterested service, the preservation of high codes of honor and ethics, still rest on the profession itself. Statutes and regulations, licensure and legal status are things of the letter, needful for public protection but not in themselves services of professional vitality and life.

The Price of Professional Liberty

GUY STANTON FORD, Ph.D., Minneapolis: How does a professional group come to be set aside and trusted with the regulation of its own profession and of its relation to society in general? It is not necessary to go back to the medieval guilds and corporations that survive in a shadowy form in the ordinances of our universities and colleges and learned professions and much more in their spirit and privileges. What we see today is that a learned profession has characteristics that set it apart and are the basis of its claim to a preferred position. The first index is that it performs some special, clearly marked and socially significant function that is not and cannot be performed by any other group or by the generality of mankind. Second, that it is a function that requires peculiar skill and definite preparation. This preparation consists always of training of a professional character, which in turn is based on a general education and is often interrelated with a period of apprenticeship. Third, that this professional group is effective in limiting its numbers, and fourth, that it has control over its membership by codes and disciplinary measures that are enforced in a way evident to the public. I call special attention to this last phrase, "codes and disciplinary measures that are enforced in a way evident to the public," because it is one of the most important from the standpoint of public confidence and one of the most neglected by every learned profession.

These criteria which I have borrowed from Professor Tauesch's volume on Professional and Business Ethics are useful. There is, however, another and more fundamental test, it seems to me. It is based on the ideals and purposes of the group or profession. If the service of the group organizations are on the level of self interest and economic and material advantage to its members, it is not and cannot be a learned profession in any proper sense. Each group, whatever its qualifications for membership, can in the long run maintain its independence and liberty of self direction only at the price of showing constantly its freedom from selfish group interests. The wise response of any profession to social change, its loyalty to the general welfare, the clarity with which it makes its professional codes comprehensible to the public which it claims to serve through and by such codes constitute the best bulwark for its cherished historic liberties.

The two great historic learned professions of teaching and preaching fail to meet at least three counts of the four mentioned; namely, there is no limitation of the number of teachers or preachers either by group control or by social prescription, nor is there more than a shadow of a uniform national standard in professional education. No national organization of either is inclusive or effective enough to set standards of educational and professional training or enforce a code of any kind. Progress toward real professional status for teachers will be slow forever. Yet they may well be the two groups who most unselfishly devote themselves by their lights, however feeble, to the service of their fellow men. My purpose is not to indict any professional group but to remind all of them that the price of their privileges and liberties as a profession lies in recognition, readjustment and thoughtful reorientation to meet the new responsibilities created by the fundamental social changes.

The medical profession is the most powerful and coherent of any of the professional groups. With its definite professional preparation and objectives, the considerable background of general education that is now prescribed and the code that it professes, it comes nearer meeting the technical definition of a profession than any other major profession. This organization and its policies and attitudes more nearly dominate the

thinking of the medical profession than does the bar association that of the lawyers. It may not be able to exclude sectarian practitioners from the healing art or discipline all the malpractitioners who flaunt a medical degree, but if it chooses it can outlaw the most distinguished member of the profession if his views contravene the accepted mores of the group. It can crush or encourage experimentation in medical education and debar its members from professional association with any one having a specific healing skill or knowledge unless the possessor has also a medical degree. In the medical profession the thoughtful citizen recognizes a group that can and does bring science into the service of the noble art of healing and alleviation.

The gratitude of the patient and of the family and friends that stand helpless but hopeful in the presence of the physician surround the profession with an aura that colors no other profession so constantly and so subtly. All these professional and personal factors make a picture that explains why the medical profession is in the perilous position of having greater liberties and privileges than any other similar group.

It is truly a perilous position because there is peril in great privilege and great responsibility. Any group in such a focal position requires a leadership and a program fully aware of all the new forces and interests and insistent demands of a dynamic society. It is important for the medical profession to know that during and since the nineteenth century the world has been revolutionized by science and technology, the development of means of communication, the concentration of population in cities, the rise of concentrated wealth and the prevalence of distributed want and poverty. More important even than all this for medicine are the changes in social attitudes. The old unrestrained individualism is gone. We have suddenly become conscious that as a nation our youth is behind us and that we are in middle age if not beyond it and that we are repeating the history of Europe without learning anything from it. In a land dedicated to democracy we are dimly aware of classes and many are shocked into blind reaction by the simple reassertion of the idea that our government was founded not only by the people but for them.

This is a new world. In medical education we can rightly boast of progress in the application of the physical and biologic sciences. But medicine is a social science dealing with one of society's greatest needs, public and private health, and the line between these two is often faint and wavering. It is a profession of such social importance that it cannot escape the impact of social change. In our modern integrated society every trade and every profession is "affected with the public interest," and none more so than the hitherto highly individualistic medical profession.

What are we as medical educators and leaders doing about it? What we are doing is next to nothing. Some years ago I analyzed typical medical student programs from entrance into high school until they were given a medical degree. I found scarcely a trace of history or any of the social sciences, i. e., political science, economics and sociology, nothing that would help to give them any understanding or interest in the changing world that would condition their whole life. It was a perfect preparation for an unsocial citizen and professional man.

There may be some who think we cover all necessary features of a doctor's social training when we administer the Hippocratic oath and hand him a little pamphlet labeled Principles of Medical Ethics distributed with the compliments of the American Medical Association. Its basis is Perceval's code of 1803 formulated in a time of cut throat rivalry in England, restated in New York in 1848 at the time of an equally bitter fight against homoeopaths and eclectics and little changed in the editions issued by this association since 1903. I am concerned that the young doctors, while retaining all the fine traditions of the profession, shall be sent forth with understanding and open minds and a new conception of service and of their paramount obligation to make more universal the scientific stores of knowledge which fail of application today in such wide areas of public and private health. Need I list as indications of society's demand for this wider application all the measures it is taking from workman's compensation, social insurance, social security and housing, to the more evident public hospitals, public dis-

penasaries, asylums, public school nurses, county nurses, student health services? In all these, many of you have been leaders. They are evidences of the growing concern of the public with matters of health. Medicine as a profession has said that it would welcome the day when matters of health assumed the same universal interest hitherto held by education alone. That is a great ideal. Its realization may be far in the future but mankind, like a great army, is on the march toward it.

The Medical School Survey

DR. HERMAN G. WEISKOTTEN, Syracuse, N. Y.: This article appeared in full in *THE JOURNAL*, March 27, page 1026.

FEBRUARY 15—AFTERNOON

DR. REGINALD FITZ, Boston, in the Chair

Report of the Survey to Individual Schools

DR. WILLIAM D. CUTTER, Chicago: In connection with our studies of the medical schools of the past two years, the Council on Medical Education and Hospitals has had in almost every case a request from the administrative officers of the school for a report of the conclusions of the Council. It would have been our desire to give a report immediately after the inspection but it was impossible in so short a time to prepare a report. We were obliged to wait until the visitation of the schools had been completed before putting into form our conclusions so that they might be returned to the faculties and officers of the schools included in the survey for their benefit and for their information. I will show on the screen a series of pattern maps or graphs covering a number of items of the organization and administration of the institutions of learning. Instead of representing on the graphs the value of any one of these features as determined by a score, there is merely a comparison of one institution with other institutions. These maps are confidential. They will be sent to the executive officers of each one of the schools, showing the conclusions of the Council with respect to that particular institution. They will not be seen by any one else. They merely represent for the benefit of that institution the observations of the Council with respect to these various activities, so that no one else is ever going to see the pattern map that is sent to you except the people to whom you are inclined to show it. It is a purely confidential expression of the conclusions of the Council with respect to the particular school. The purpose in sending these maps is merely to give you the information which the Council has gleaned from study of the various institutions that were included in the survey. No action of the Council is based on this map, and no action will be based on it. It is intended solely for your information and for your guidance.

SYMPOSIUM ON CANCER

The Biology of Cancer

C. C. LITTLE, Sc.D., Bar Harbor, Maine: I should like to bring to attention what might be called the genetic point of view as a basic principle in cancer research. There is no species of domesticated animal in which the genetics is so thoroughly misunderstood as in the case of man, and that situation is likely to continue far beyond our lifetime. The chemist would be helpless in his attempt to analyze unknown material if he didn't have known chemical agents on the shelves of his laboratory to which he could turn as assistance in analyzing the unknown. The biologist, in the past fifteen years, has been given the tools by which he can approximate that result. I believe that by the use of genetics, it has been possible very definitely to measure the variations which occur in the tumor and it has been possible to measure the degree of differentiation possessed by the tumor. It was possible as early as 1922 to show in work Dr. Strong did with me that two tumors which looked exactly alike under the microscope could give very different physiologic effects and the very different genetic ratios. We sent slides to two pathologists and they said they were the same tumors, but we obtained different genetic results after inoculating the tumors. This gave a preliminary and unsatisfactory result, but it shows the relationship of tumors not detected by any physiologic method of analysis.

I have been talking about inoculated tumors and the way in which biologic principles can be used to bring them into the

field of research. The same principle of pure strains holds good in spontaneous tumors. It has been known for years that genetics played an extremely important part in determining whether a given family of animals would or would not develop tumors. The factor of age in connection with spontaneous tumor incidence is interesting. It is known from the statistical material available on human beings that there is a marked difference in age incidence of such types of tumors as those of the female reproductive type, those of the digestive system and those of the skin. It is evident that those types of tumors are biologically different from one another. Although they may have something in common, there are enough different factors to make the mean age of incidence of tumors of the breast and of the uterus different from the tumors of the digestive tract and those of the type of skin tumors which increase in relative incidence up to the duration of human life.

It seems to me that we have a suggestive line of research that will drive us outside of the chromosomes and possibly into the cytoplasm of the egg to find out whether there is difference in sensitivity of this cytoplasm to various internal stimulants which may lie at the base of cancer.

When carcinogenic substances are used in minute quantities that approximate the degree that one might expect to find them present in the body, there are differences that tend to show up in the reaction of the animal to the carcinogenic agent. We do not know the limits to which one may expect these stimulants to occur naturally in the body, but that there is a genetic difference in human material and in mice is undoubted. That this difference in the state of nature is an important difference in determining whether the individual will or will not have a cancer seems to be undoubted. The cancerous change appears to be one to which almost any tissue can be pushed if maltreated and irritated for a long enough period. Sometimes, however, there are natural limits of irritation in the life of the normal mammal.

In experimental medicine today it is largely a deliberate handicap if an institution chooses to use material that is not genetically controlled and not as uniform as it is possible to make it. It is just as antiquated to use mixed material concerning the ancestry of which one knows nothing as it would be to revert to the old methods of surgery.

The Pathology of Cancer

DR. FRANCIS CARTER WOOD, New York: There have been vast changes in our ideas of the causes and nature of cancer in the hundred years since Johannes Müller first studied the crude teasings and scrapings of neoplasms. We are no longer intensely interested in morphology, except as a means of practical diagnosis. Probably all types of human cancer have been seen and described. The only thing left is to codify our knowledge, agree on our nomenclature, and publish the data in convenient form. As a beginning, the International Union Against Cancer has authorized me to prepare a diagnostic atlas of tumors illustrating all the known types of cancer and, so far as possible, their morphologic variants. Opposite the picture of each type will be the synonyms in several languages, which may be subject to change from time to time, though the broad outlines of classification are fairly well established.

The present view is that biology is more important than morphology. The remaining importance of morphology is to be able to inform the surgeon or the radiotherapist what the classified experience of his predecessors has been concerning the life history of neoplasms bearing a certain morphology. I have made certain checks on standard sets of sections, which show that no two pathologists will make exactly the same classification. Unfortunately, large statistics of carefully studied tumors which have been grouped by the same individual are still lacking.

Grouping, on the whole, does not tell the fate of the individual who possesses a tumor but rather the fate of a group of individuals with the same kind of a tumor. It is like insurance statistics. Life tables do not prophesy what will occur to the individual but only to large numbers, and even under these circumstances an epidemic may completely upset the expectation of life of a definite group. These deficiencies are well recognized and attempts have been made by many workers in the field to combine the morphology of the tumor with its position in a

given organ, its extension to nodes and other clinical characteristics into a more useful prophecy as to the fate of the patient. It is of the greatest importance that more of such thoroughly observed material be collected and studied, using all the characteristics on which to base a prognosis.

Morphology has been used to help the radiologists in determining the probable sensitivity of a tumor to radiation. Morphology does not necessarily run parallel with tumor susceptibility, even in neoplasms of exactly the same morphology. The reason for this is that no two tumors, even of the same morphology, necessarily spring from a cell with exactly the same biologic qualities. Certain broad lines are now available. The radiologic differences between the behavior of a basal cell tumor of the skin, its close relative the squamous cell type, and the mixtures of the two form a fairly reliable guide. It is known, for example, that the lymphoblastic group are sensitive to radiation, though such sensitivity is not necessarily correlated with curability, for it is far easier to cure with radiation a squamous cell carcinoma, because of its tendency to remain local, than to obtain one of the rare cures of the sensitive lymphosarcoma. The reticulum cell group of connective tissue tumors are also now known to be sensitive, but they also have the habit of extending rapidly while the primary tumor may disappear under treatment. The undifferentiated types, while more malignant from a surgical standpoint, are usually more sensitive from the radiation aspect, but in neither case does any large body of information exist on carefully observed material. It is well known that the glandular forms of carcinoma are resistant to radiation, those, for example, of the lung and gastrointestinal tract. Even in carcinoma of the uterus there is some disagreement as to the effects on all types. Whether the combination of irradiation with subsequent surgery in this field and also in carcinoma of the cervix offers any better salvage than with irradiation alone is still open to discussion. There is some evidence that it is difficult to destroy all the cells even in the cervical neoplasms of the squamous type and that the five year results are somewhat better if the hysterectomy is done shortly after the radiation treatment. Only future observations will render it possible to obtain reliable figures. There is some contradiction, too, in the cervical neoplasms, for if undifferentiated carcinomas are considered as sensitive and the adenocarcinomas as resistant, the clinical results are not comparable, because the adenocarcinomas may metastasize to the pelvic tissues late and the highly differentiated and smaller celled forms metastasize early. Thus a paradox is obvious; the more malignant type of neoplasm may be more easily curable by irradiation. But here, too, final conclusions await greater experience.

The danger of grouping and its application to sensitivity is the tendency to dogmatism in saying that a group I tumor is resistant and must be operated on while a group IV tumor is sensitive and must be treated with radiation. It is being slowly realized that dogmatism in this field is not always rewarded by good results. For these reasons it is of the utmost importance that our future records of large groups be published accompanied by photographs of typical portions of the growth, so that the results obtained in different clinics may have some basis for comparison. Every hospital pathologist should avoid wordy descriptions of tumors and spend his time in seeing that more sections are prepared and preserved under such conditions of permanence that they will always be available when the final check up comes. Even insurance companies can well afford to demand and file slides of all those applying for insurance who have had an operation for any form of neoplasm whether benign or malignant. It is also essential that enough slides be available so that they can be exchanged, for patients often travel in these days from clinic to clinic and some of the samples that one sees of bad technic are revealing in the impossibility of making a diagnosis from the so-called stained sections.

The experimental use of certain chemicals, both of unknown nature as secreted by parasites and the recently discovered hydrocarbons with which the name of Cook of the Royal Cancer Hospital in London will always be associated, has caused a change in our notions as to the hereditary possibilities. It seems probable that ultimately we may have to give up the idea of genetic relationships of cancer, except such as control the length of life of the animal. The sum total of such experi-

mental work has been to show that no genetic correlation with the initiation of cancer can be discovered and that the only factors which are correlated with the appearance of a neoplasm are the length of life of the animal and the amount of the irritation. We might as well give up saying that we know nothing about the cause of cancer, because we know just as much about it as we do, of the cause of tuberculosis, for instance.

The suggestion is made that because tumors have a variable morphology there must be variable causes, but we know now that a parasitic worm in the liver of the rat will incite seventeen different varieties of tumor, including chondromas and osteogenic sarcomas. We find that dibenzpyrene and methylcholanthrene will produce, as far as one can see, tumors in any organ in which they are known to occur. We are beginning to understand the results of tissue culture, which have shown that the connective tissues of the body contain not a single type of cell but a great variety of cells and so can see an explanation for the extraordinary group of connective tissue tumors that are now appearing. In animals composite tumors are not uncommon. An irritant placed in the breast will cause a carcinoma and at the same time a sarcoma, so there is produced what the Germans term a "collision" tumor. Secondly, cells which have hitherto not been thought to exist in such adult connective tissue of the subcutaneous regions may react to these concentrated stimuli and produce tumors of striated or unstriated muscle, of fat tissue, and of a type hitherto strictly confined to the bones, the osteogenic sarcomas, even including cartilage.

Speaking of these bone types, the injection of radioactive material has now been shown to be a fairly effective means of producing osteogenic sarcomas of various types in the bones of laboratory animals. Radium, mesothorium and thorium dioxide sol have all been shown to be admirably effective in the course of time in this regard.

There has been nothing more interesting lately from a tumor point of view than the discovery by Zondek and Ferguson that teratoid tumors of the testicle can be diagnosed with the Aschheim-Zondek reaction. No doubt all tumors give rise to small amounts of gonadotropic substance, but it is not detectable by the ordinary tests, so this phenomenon is chiefly valuable in checking the nature of suggestive uterine and testicular tumors, and also for prognosis, as a positive reaction points to a recurrence. The ovarian hormones have been accused of many crimes, but gradually sanity is returning and a general agreement seems to have been reached to postpone any further statements until more is known on the subject. The view is gaining ground that the type of tumor is not at all determined by the genetic constitution of the host, as the geneticists are fond of stating, but that it is the cell which yields to the irritant by an abnormal type of growth, a somatic mutation or whatever one chooses to call it; in other words, the formation of a new race of cells that makes the tumor what it is. This fact is beautifully demonstrated even in human pathology. All of us have seen cases of multiple carcinoma. I recall an instance in which a patient had a quiescent basal cell carcinoma, a carcinoma of the gastro-intestinal tract, both of which were relatively benign, and then a melanoma developed, which carried the patient off rapidly. Here were three types of neoplasm in a single body, which certainly was genetically homozygous to itself, and because three different types of cells happened to be irritated and underwent a malignant change, three different types of cell biology were represented in the neoplasms. These are some reasons why those who are doing experimental work are not especially interested in mere morphology. What excuse has a rat to have an osteogenic sarcoma in his liver? It is obvious that if morphology and genetics do not help us, the door is opening for the chemist. When Warburg showed that the cancer cell metabolized dextrose in a different fashion from the healthy, uninjured, homologous cell, he did not explain the cause of cancer, but he explained why a cancer cell can get along under circumstances which the healthy cell finds difficult for life. When Cook discovered the carcinogenic substances and extracted dibenzpyrene from coal tar, he explained a type of cancer that has occurred for many years in human beings and placed in the hands of the laboratory worker a means of obtaining an immense number of primary tumors. The grafted tumors are merely a race of cells under cultivation. The advantage of obtaining by grafting isolated cells of cancer of

various types, at short notice, has resulted in a great change in our ideas, but also, owing to lack of training of those who do cancer research, has produced a good deal of rubbish which has greatly puzzled those not familiar with laboratory technic. Do the medical schools teach anything of what I have spoken? From many years' experience with interns, I would say that they seem to know less of cancer than almost any other subject in medicine, and yet this disease is now the second most important cause of death.

(To be continued)

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

ALABAMA: Montgomery, June 22-24. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

ARIZONA: Phoenix, April 6-7. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

ARKANSAS: *Basic Science.* Little Rock, May 3. Sec., Mr. Louis E. Gebauer, 701 Main St., Little Rock. *Medical (Regular).* Little Rock, June 17-18. Sec., Dr. A. S. Buchanan, Prescott. *Medical (Eclectic).* Little Rock, May 11. Sec., Dr. Clarence H. Young, 1415 Main St., Little Rock.

CALIFORNIA: *Reciprocity.* San Francisco, May 9. *Examinations.* San Francisco, June 28-July 1, and Los Angeles, July 19-22. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

COLORADO: Denver, April 6. Sec., Dr. Harvey W. Snyder, 422 State Office Bldg., Denver.

CONNECTICUT: *Basic Science.* New Haven, June 12. *Prerequisite to license examination.* Address State Board of Healing Arts, 1895 Yale Station, New Haven.

DELAWARE: Dover, July 13-15. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, Dover.

DISTRICT OF COLUMBIA: *Basic Science.* Washington, June 28-29 (probable dates). *Medical.* Washington, July 12-13. Sec., Commission on Licensure, Dr. George C. Ruhland, 203 District Bldg., Washington.

FLORIDA: Jacksonville, June 14-15. Sec., Dr. William M. Rowlett, Box 786, Tampa.

HAWAII: Honolulu, July 12-15. Sec., Dr. James A. Morgan, 48 Alexander Young Bldg., Honolulu.

IDaho: Boise, April 6. Commissioner of Law Enforcement, Hon. J. L. Balderston, 205 State House, Boise.

ILLINOIS: Chicago, April 6-8, June 22-25 and Oct. 19-21. Superintendent of Registration, Department of Registration and Education, Mr. Homer J. Byrd, Springfield.

INDIANA: Indianapolis, June 22-24. Sec., Board of Medical Registration and Examination, Dr. William R. Davidson, 301 State House, Indianapolis.

IOWA: *Basic Science.* Des Moines, April 13. Sec., Prof. Edward A. Benbrook, Iowa State College, Ames. *Medical.* Iowa City, June 8-10. Dir., Division of Licensure and Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines.

KANSAS: Topeka, June 15-16. Sec., Board of Medical Registration and Examination, Dr. C. H. Ewing, 609 Broadway, Larned.

KENTUCKY: Louisville, June 9-11. Sec., State Board of Health, Dr. A. T. McCormack, 532 W. Main St., Louisville.

MARYLAND: *Medical (Regular).* Baltimore, June 15-18. Sec., Dr. John T. O'Mara, 1215 Cathedral St., Baltimore. *Medical (Homeopathic).* Baltimore, June 8-9. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore.

MICHIGAN: Ann Arbor and Detroit, June 9-11. Sec., Board of Registration in Medicine, Dr. J. Earl McIntyre, 202-204 Hollister Bldg., Lansing.

MINNESOTA: *Basic Science.* Minneapolis, April 6-7. Sec., Dr. J. Charnley McKinley, 126 Millard Hall, University of Minnesota, Minneapolis. *Medical.* Minneapolis, April 20-22. Sec., Dr. Julian F. Du Bois, 350 St. Peter St., St. Paul.

MISSISSIPPI: Jackson, June. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

MONTANA: Helena, April 6. Sec., Dr. S. A. Cooney, 7 W. 6th Ave., Helena.

NEBRASKA: *Basic Science.* Omaha, May 4-5. *Medical.* Omaha, June 8-9. Dir., Bureau of Examining Boards, Mrs. Clark Perkins, State House, Lincoln.

NEVADA: Carson City, May 3-4. Sec., Dr. John E. Worden, Box 630, Carson City.

NEW JERSEY: Trenton, June 15-16. Sec., Dr. James J. McGuire, 28 W. State St., Trenton.

NEW MEXICO: Santa Fe, April 12-13. Sec., Dr. Le Grand Ward, Box 693, Santa Fe.

NEW YORK: Albany, Buffalo, New York and Syracuse, June 28-July 1. Chief, Professional Examinations Bureau, Mr. Herbert J. Hamilton, 315 Education Bldg., Albany.

NORTH CAROLINA: Raleigh, June 21. Sec., Dr. Ben J. Lawrence, 503 Professional Bldg., Raleigh.

NORTH DAKOTA: Grand Forks, July 6-9. Sec., Dr. G. M. Williamson, 4½ S. 3rd St., Grand Forks.

OKLAHOMA: Oklahoma City, June 9-10. Sec., Dr. James D. Osborn Jr., Frederick.

OREGON: *Medical.* Portland, June 15-17. Sec., Dr. Joseph F. Wood, 509 Selling Bldg., Portland. *Basic Science.* Corvallis, July 17. Sec., State Board of Higher Education, Mr. Charles D. Byrne, University of Oregon, Eugene.

PENNSYLVANIA: Philadelphia and Pittsburgh, July 6-10. Sec., Board of Medical Education and Licensure, Dr. James A. Newpher, Education Bldg., Harrisburg.

SOUTH CAROLINA: Columbia, June 22. Sec., Dr. A. Earle Boozer, 505 Saluda Ave., Columbia.

SOUTH DAKOTA: Rapid City, July 20-21. Dir., Division of Medical Licensure, Dr. B. A. Dyar, State Board of Health, Pierre.

VERMONT: Burlington, June 16-18. Sec., Board of Medical Registration, Dr. W. Scott Nay, Underhill.

VIRGINIA: Richmond, June 17-19. Sec., Dr. J. W. Preston, 28½ Franklin Road, Roanoke.

WISCONSIN: Milwaukee, June 29-July 2. Sec., Dr. Henry J. Gramling, 2203 S. Layton Blvd., Milwaukee.

WYOMING: Cheyenne, June 7. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

NATIONAL BOARD OF MEDICAL EXAMINERS SPECIAL BOARDS

Examinations of the National Board of Medical Examiners and Special Boards were published in THE JOURNAL, March 27, page 1137.

Arkansas November Examination

Dr. A. S. Buchanan, secretary, State Medical Board of the Arkansas Medical Society, reports the written examination held in Little Rock, Nov. 10, 1936. The examination covered 12 subjects and included 120 questions. An average of 75 per cent was required to pass. Two candidates were examined, both of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of Arkansas School of Medicine.....	(1936)		78.9
Tulane University of Louisiana School of Medicine....	(1935)		81.7

Nine physicians were licensed by reciprocity and one physician was licensed by endorsement from June 20 through October 21. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Tulane University of Louisiana School of Medicine....	(1928)		Texas,
(1935) Louisiana, Oklahoma			
University of Michigan Medical School.....	(1925)		Michigan
Washington University School of Medicine....	(1925),		(1935) Missouri
Memphis Hospital Medical College.....	(1911)		Mississippi
University of Tennessee			Tennessee
Vanderbilt University Sc			Tennessee

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
Cornell University Medical College.....	(1934)		N. B. M. Ex.

Kentucky Reciprocity and Endorsement Report

Dr. A. T. McCormack, secretary, State Board of Health of Kentucky, reports 14 physicians licensed by reciprocity and 3 physicians licensed by endorsement from Aug. 7 through Dec. 22, 1936. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Howard University College of Medicine.....	(1935)		Missouri
Chicago College of Medicine and Surgery.....	(1909)		Illinois
University of Maryland School of Medicine and College of Physicians and Surgeons.....	(1931)		Maryland
Harvard University Medical School.....	(1917)		Mass.
University of Michigan Medical School.....	(1929)		Michigan
Washington University School of Med. ..	(1930)		Iowa, Missouri
Eclectic Medical College, Cincinnati.....	(1935)		Ohio
University of Cincinnati College of Medicine.....	(1935)		Ohio
Meharry Medical College.....	(1928)		Tennessee
University of Tennessee College of Medicine.....	(1935, 2),		(1936) Tennessee
Vanderbilt University School of Medicine.....	(1935)		Tennessee

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
College of Medical "			M. Ex.
Cornell University "			M. Ex.
Vanderbilt Universit			M. Ex.

Tennessee December Examination

Dr. H. W. Qualls, secretary, Tennessee State Board of Medical Examiners, reports the written examination held in Memphis, Dec. 16-17, 1936. The examination covered 8 subjects and included 80 questions. An average of 75 per cent was required to pass. Nineteen candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
College of Medical Evangelists.....	(1936)		86.4
Northwestern University Medical School.....	(1935)		82.6
University of Tennessee College of Medicine.....	(1936)		81.5,
82, 82.4, 82.5, 83, 83.1, 84, 84.3, 85.1, 85.6, 86, 86,			86.1, 86.3, 86.8, 87.1
Queen's University Faculty of Medicine.....	(1931)		86.8

Six physicians were licensed by endorsement from November 12 through December 21. The following schools were represented:

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
Johns Hopkins University School of Medicine.....	(1912)		Maryland
Columbia Univ. College of Physicians and Surgeons.....	(1933)		New York
University of Oklahoma School of Medicine.....	(1934)		Oklahoma
University of Nashville Medical Department.....	(1908)		S. Carolina
University of Tennessee College of Medicine.....	(1931)		Mississippi
Medical College of Virginia.....	(1912)		Virginia

Book Notices

Bright's Disease and Arterial Hypertension. By Willard J. Stone, B.Sc., M.D., F.A.C.P., Clinical Professor of Medicine, School of Medicine, University of Southern California, Los Angeles. Cloth. Price, \$5. Pp. 352, with 32 illustrations. Philadelphia & London: W. B. Saunders Company, 1936.

This excellently printed volume is a condensed statement of the well known facts regarding Bright's disease. It is beautifully illustrated with photomicrographs both in color and in black and white. The style is clear and lucid. The organization and arrangements are logical but there appears to be an overemphasis of classification in an attempt to divide the various types of renal disease into small semidemarked entities. The first half of the book includes a brief historical sketch, classification of Bright's disease, discussion of renal functions and methods of testing these, the water balance of the body, acidosis, uremia, laboratory procedures and pathologic consideration. The remainder of the book is concerned with a discussion of the so-called specific forms of the disease in its various subdivisions. These subdivisions are further separated into acute, second and terminal stages. Appended are brief one paragraph case reports of 140 cases in which necropsies have confirmed the clinical diagnosis. The discussion of the physiology of the kidney is sound but rather brief and sketchy in its presentation. Weakest of all is the discussion of hypertension both independently and in its relation to renal disease. About fifty pages is devoted to those forms of nephritis in which hypertension is a conspicuous problem and/or to hypertension per se. This discussion is inadequate to justify the second half of the title of the book. There appears to be a lack of correlation between the physiologic consideration, phenomena of Bright's disease and its treatment. In some places treatment is considered fully, in others presented most sketchily. The discussion of treatment is probably orthodox everywhere in the sense that it conforms with the general trend of opinion. One fails, however, to find any adequate presentation of the reasons why such treatment, which is advised, should be instituted. On the whole, this book can be considered a good summary of the known or largely assumed facts and theories of Bright's disease, and in no place could a student or nonspecialist be led astray. For the student of renal disease and for the investigator, the book is a bit of a disappointment in that it really presents nothing new.

Trachoma. By A. F. MacCallan, C.B.E., M.D., F.R.C.S., President of the International Organization against Trachoma. Embodying the Hunterian Lecture at the Royal College of Surgeons of England, 1936, on the Surgery and Pathology of Trachomatous Conjunctivitis. Cloth. Price, £1. 1s. Pp. 225, with 19 illustrations. London: Butterworth & Co., Ltd., 1936.

Here is an important piece of work by the foremost trachomatologist of these times and as such must be given due consideration. The book is well printed on a somewhat different grade of paper than is commonly found in American textbooks. The majority of the illustrations are in color and all are well done. After the introduction there are chapters on clinical manifestations, sequelae, complications, differential diagnosis, treatment, pathologic anatomy, epidemiology and historical aspects. A complete author and subject index concludes the volume.

In 1903 MacCallan was called from London to assume charge of the newly started governmental endeavor to control trachoma in Egypt. For twenty-one years he worked and built up an organization which now includes thirty permanent ophthalmic hospitals, fourteen traveling ophthalmic hospitals under canvas, twenty ophthalmic departments in government general hospitals, and thirty-two daily ophthalmic clinics in government schools. These institutions are staffed almost exclusively with Egyptian physicians trained by MacCallan. During 1934, 928,215 new patients were treated at these hospitals, and on them were performed 94,681 operations for trachoma, cataract and glaucoma. Truly a monument of noble proportions.

It would seem presumptuous to question the word of a trachomatologist as eminent as the author, but is it universally accepted that corneal involvement is necessary to establish the diagnosis of trachoma? This point is insisted on by MacCallan, who properly utilizes the advantages of biomicroscopy whenever possible. Tarsectomy, which has been entirely rejected in this

country, is still counted among the therapeutic measures advocated in certain circumstances by the author. Again no mention is made of the well known absence of trachoma among the American Negroes, although it undoubtedly exists among the African Negroes, as shown by an analysis of the distribution of the disease throughout the British colonies.

The book is too full of material to permit of comment on any special phase, material garnered from a decade of rich personal experience. To one less well versed in the treatment of trachoma than the author, the value of the text would be enhanced by somewhat greater attention to therapeutic measures and diagrammatic illustrations of the various operative procedures employed. But the chapters on pathologic anatomy and epidemiology more than make up for any of the minor deficiencies noted. The book is a vast improvement over the author's "Trachoma and Its Complications in Egypt" of 1903, for it contains a thorough digest and bibliographic references to the important work of the past decade. It is particularly pleasing to note the high value placed on Thygeson's work but yet the cautious refusal to accept etiologic conclusions that have not been proved to the author's satisfaction.

As said in the beginning, here is an important book. It must be read by every ophthalmologist who sees or may see even a single case of trachoma; it should form the Bible of the public health medical officers engaged in antitrachomatous campaigns; and it can be studied with profit by every epidemiologist.

Holt's Diseases of Infancy and Childhood: A Textbook for the Use of Students and Practitioners. By the late L. Emmett Holt, M.D., and John Howland, M.D. Revised by L. Emmett Holt Jr., M.D., Associate Professor of Pediatrics, Johns Hopkins University, Baltimore, and Rustin McIntosh, M.D., Carpenter Professor of Diseases of Children, Columbia University, New York City. Tenth edition, revised. Cloth. Price, \$10. Pp. 1,240, with 205 illustrations. New York & London: D. Appleton-Century Company, Incorporated, 1936.

The first edition of this volume by the late L. Emmett Holt appeared in 1897. Subsequent editions were revised by John Howland; the present edition was prepared by L. Emmett Holt Jr. and Rustin McIntosh. In the present revision the authors have endeavored as much as possible to retain the personal opinions and attitudes of the original authors. They supplement the text with a bibliography and add much material on pathogenesis. So extensive have been advances in the field of nutrition, the blood and allergy and also on some of the infectious diseases and on endocrinology that certain sections have been rewritten completely and extensive revisions made in others. Perhaps a dozen associates have been called on by the authors for the revision of some of the special sections of this book. Its usefulness is manifest from its record of sales.

Handbuch der mikroskopischen Anatomie des Menschen. Herausgegeben von Wilhelm v. Möllendorff. Band V: Verdauungsapparat. Teil 3: Zähne, Darm, Atmungsapparat. Bearbeitet von W. Bargmann et al. Paper. Pp. 908, with 426 illustrations. Berlin: Julius Springer, 1936.

The von Möllendorff Handbuch in seven volumes constitutes a comprehensive and reliable review of the results of research in microscopic anatomy up to the present time. This book is the third part of the fifth volume and it deals with part of the digestive apparatus, namely, the teeth and the intestine, and also with the respiratory apparatus. The section devoted to the intestine has been written by Dr. Viktor Patzelt of Vienna and includes 448 pages and 169 illustrations. The review of literature is exhaustive and is arranged under the logical headings (1) general structure, including evolution and functional differentiation, (2) development, (3) constituent parts of the intestine—their evolution and function in the animal series, and (4) the contents of the intestine. The section on the teeth is written by Dr. Josef Lehner and Prof. Hanns Plenck of Vienna. It includes 260 pages with 119 illustrations. It deals with (1) gross anatomy, theories of origin and of the complex form of teeth; (2) phylogenesis; (3) development of the teeth and of the jaw, under the headings of enamel, dentin, cement, pulp and periodontal membrane. The section on the respiratory apparatus is by Dr. R. Heiss of Königsberg. It includes ninety pages and 101 illustrations. There follows an appendix on the lung alveoli by Dr. Bargmann of Zurich covering sixty pages, with thirty-seven illustrations. The review of the literature is thorough and the bibliography accompanying each section is a valuable contribution. At the end there is a twenty-five page index of authors and a twenty-three-

page index of subjects considered. The book constitutes a storehouse of information, covering the microscopic anatomy of the vertebrate series of animals. It will be an exceedingly valuable and almost indispensable reference book for any one wishing to study the literature on any particular structure in the field covered by the book. The format and the illustrations are in accord with the pleasing and satisfactory manner that is customary with the publications of Julius Springer.

Oral Diagnosis and Treatment Planning: A Text for the Dental Student; A Reference Book for the Practitioner and Medical Student. By Kurt H. Thoma, D.M.D., Charles A. Brackett Professor of Oral Pathology in Harvard University. Cloth. Price, \$6. Pp. 379, with 533 illustrations. Philadelphia & London: W. B. Saunders Company, 1936.

The subtitle properly describes this book as a text for the dental student, a reference book for the practitioner and medical student. For the former it is indispensable; in addition it is a handy and usable guide for both physicians and dentists in their efforts to identify and evaluate the diseases and lesions of the oral cavity. It begins with a brief statement of instructions for its use. Part I, on the theory of diagnosis and treatment planning, is covered in twenty-one pages. Part II, seventy-five pages, deals with methods of examination and includes the preparation of the clinical history, general and special examinations, laboratory tests and roentgenographic technic as well as interpretation. The directions for all examinations and tests are more than adequate. Part III comprises the bulk of the text and is concerned with the clinical diagnosis of dental and oral diseases. The organization of this part is such that it is quite possible, given even a single symptomatic clue, to set up a diagnostic problem that is relatively simple so that the chances for a correct solution are materially enhanced. There is an eleven page bibliography, which has been carefully selected to include the best in recent literature bearing on the subject. The index is unusually complete and is arranged to facilitate rapid location of pertinent matter in the body of the book. The copious illustrations are excellent and highly helpful. Their relatively small size does not detract from their value, and this has made it possible to cover visually a tremendous amount of subject matter without unduly increasing the size of the book. The author has made an important and helpful contribution to the art of oral diagnosis.

Essentials of Modern Medical Treatment. By Vincent Norman, M.D., M.R.C.P., F.R.C.S. Cloth. Price, 10s. 6d. Pp. 200. London: Hutchinson's Scientific and Technical Publications, 1936.

This aims to provide the busy general practitioner with a work for ready reference on treatment. It is surprising how much practical information is packed into a small volume. Ripe experience shines through many of its maxims; e. g., "In sciatica do not attempt to stretch the nerve by extending the leg; it does more harm than good." Or, for obstinate cases of trigeminal neuralgia, "consider injection of 30 minims of alcohol, 90 per cent. This should only be done by an expert, and in any case risk of subsequent blindness is considerable. Most satisfactory treatment for intractable cases is partial ganglionectomy, which leaves out the inner and ophthalmic fibers, and so avoids risk of keratitis." In epilepsy "the ketogenic diet is only of limited benefit." In Ménière's disease, phenobarbital is recommended for the prevention of the attacks. In connection with the therapy of paralysis agitans the interesting statement is made that larger doses of scopolamine may be given if combined with pilocarpine. In the therapy of children's convulsions the author pins his faith on the warm, not hot, bath, vigorous rubbing of the skin, a warm soapuds enema, and a dose of castor oil. He does not advise bromide and chloral, as he finds them too depressing. These examples, culled at random from chapter I on diseases of the nervous system, may suffice to show how rich in information on therapy this book is. Unfortunately, the author's training in prescribing has come down from the days when nearly all medicine had to have a horrible taste. With the frequent administration in liquid dosage form of quinine sulfate, strychnine or ferric chloride, his patients certainly have a bitter and rather nasty time of it. There being no such thing as the "Council on Pharmacy and Chemistry" in Great Britain, the author may possibly be excused if his pages reveal a greater partiality to proprietary medication than would be considered desirable in this country in a scientific book on medical treatment.

Urological Roentgenology: A Manual for Students and Practitioners. By Milley B. Wesson, M.D., and Howard E. Ruggles, M.D., Roentgenologist to University of California Hospital. Cloth. Price, \$5. Pp. 269, with 227 illustrations. Philadelphia: Lea & Febiger, 1936.

This is an excellent volume for the beginner in urography, as it contains a remarkable collection of well reproduced pyelograms. Many of these urograms will be of interest to the most expert urologist also. This book shows the result of having been long in preparation, however, as certain advice and discussions are now obsolete. The expense of using intravenous preparations for retrograde pyelograms is discussed. Twenty per cent hippuran costs about 1 cent per cubic centimeter, which makes the medium for the average pyelogram cost from 10 to 15 cents; this is certainly not excessive. The great value of excretory urography in certain conditions is not properly stressed. Certainly this is of use in cases other than those in which cystoscopy is impossible. The text is not of the same high quality as the illustrations, and one doubts whether discussion of workmen's compensation is proper in a book entitled "Urological Roentgenology." The subject as a whole, with the exception of chronic renal infections, is well covered. The last illustration is printed upside down for no apparent reason. A good index is appended.

Experimental Studies on a Transmissible Myelomatosis (Reticulosis) in Mice. By Otto Kaalund-Jørgensen. Paper. Price, 12 kronor. Pp. 142, with 25 illustrations. Copenhagen: Levin & Munksgaard, 1936.

The fact that leukemia occurs in mice was observed by Eberth in 1878. Since that time there have been numerous studies of leukemia, lymphosarcoma and leukosarcoma in the smaller laboratory animals. Of late it has been found that lymphatic and myeloid leukemia can be transmitted by inoculation in inbred strains of mice but is possible only with living cells and in the author's experiments mainly in animals that were previously irradiated. The conclusion has been drawn by Furth and others from their studies that lymphomatosis and also myelosis represent a neoplastic process. The author, while he surveys fully the conclusions of others, has confined his own observations to a leukemic disease in which myeloblasts are abundant in the blood, a myelomatosis in contrast to Furth's myelosis, in which myelocytes predominate. The pathologic changes in the blood and organs of the mice with myelomatosis were carefully studied. Curiously the spleen is not enlarged in this condition though it is regularly enlarged in the lymphomatoses. The most abundant pathologic cells in the blood are, as has been said, classified as myeloblasts. No peroxidase reaction was given by these cells, although the occasional myelocytes and ordinary leukocytes gave positive reactions. It is possible that this lack of reaction is due to the extreme immaturity of the cells. The author regards the type of myelomatosis studied as a systemic neoplastic process intimately associated with the reticulum. The volume ends with a long bibliography and a series of twenty-five drawings and photographs and forms an excellent contribution to a subject which, in spite of the large amount of work that has been done on it in the last few years, is still obscure in many aspects.

Skin Diseases in Children. By George M. MacKee, M.D., Professor of Clinical Dermatology and Syphilology, New York Post-Graduate Medical School, Columbia University, New York, and Anthony C. Cipollaro, M.D., Associate in Dermatology and Syphilology, New York Post-Graduate Medical School, Columbia University, New York. Cloth. Price, \$5.50. Pp. 345, with 153 illustrations. New York & London: Paul B. Hoeber, Inc., 1936.

This book can well be recommended for what it is intended to be, a practical useful edition for practitioners in general medicine. It is a clinical presentation throughout, the anatomy, physiology and pathologic descriptions being omitted, and the authors also avoided emphasis on precise dermatologic refinements. For these the reader is referred to larger dermatologic textbooks. The classification employed is a convenient one; there is a chapter on diseases in which pyogenic bacteria are etiologic factors, and others concern diseases due to fungi, drug eruptions, the eczema group, erythema group, new growths and congenital defects. The discussions are in good balance, with proper emphasis on the diseases that are encountered most frequently, and they are described plainly and with clear word pictures. The exanthems are omitted. The treatment is orthodox, and throughout there are prescription formulas that

can be compounded readily by any pharmacist. The illustrations, all in black and white, are well selected. Altogether the book is a sound introduction to practical clinical dermatology, with especial emphasis on conditions that are encountered in children.

La diabetes en la practica. Por el Dr. Francisco Gnecco Mozo. Paper. Pp. 107. Bogota: Editorial Cromos, 1936.

This is intended for medical students, especially of Colombia. The purpose of the author is to simplify the whole subject of diabetes, a knowledge of which was previously available to them only in some gigantic treatise on the disease. In opening the subject the author prefers to substitute, in preference to a long list of symptoms, numerous clinical cases for clarification and diagnosis of diabetes, following this by a summary of local disturbances referable to diabetes skin, gastro-intestinal and genito-urinary tracts, neurologic, cardiovascular and respiratory systems and trophic changes. This approach to the subject is original and excellent because it recognizes the great and confusing variety of symptoms by which the disease may be first manifested. In the etiology of diabetes he speaks of senile lassitude of the pancreas because of the greater frequency of diabetes in persons over 40 years of age. He fails to discuss satisfactorily hepatic glycogen disturbances as a possible contributing etiologic factor. One is under the impression that only the pancreas is at fault in diabetes. He also speaks of two forms of diabetes, that of youth with rapid evolution and that of mature age of longer duration, a confusion because, while true as a generalization, it is not necessarily true in every case. The author unfortunately speaks of the drugs Sintalina-B and Copalchi in the treatment of "mild cases of diabetes" and affirms their efficacy in doses advocated by their manufacturers. That no drug on the market today can control diabetes, clinical research amply shows. On the other hand, he does not speak of protamine insulin, the new slow acting insulin compound, nor does he describe sufficiently the effects of plain or ordinary insulin on the carbohydrate metabolism. Diets are not thoroughly gone into. Since this manuscript is for students, it should be more thorough in describing disturbances of carbohydrate metabolism and the complications of diabetes. The author hopes that the good seed of curiosity will be sown in this manuscript so to inspire later on a greater and more worthy work in diabetes. No doubt this will happen. On the whole, students will acquire much from this manual that will be helpful to them.

Digestion and Health. By Walter B. Cannon, George Higginson Professor of Physiology, Harvard Medical School. Cloth. Price, \$2. Pp. 160, with 14 illustrations. New York: W. W. Norton & Company, Inc., 1936.

Dr. Cannon is internationally known as a contributor to our knowledge of physiology. He is known for his ability in expressing his knowledge equally to scientific and to public audiences. In some fundamental essays, first developed in lecture form, he traces the nature of appetite and hunger, the nature of thirst, our knowledge of digestion and bodily vigor and the relationship of pain, worry and excitement to indigestion. In an epilogue he shows the importance of digestion in the body economy, adding it to the lungs, the heart and the brain as the fundamental systems of the human body.

It is significant that the lectures which form the basis of this volume are characterized as the Beaumont lectures, thus adding still further to the fame of that American founder of our knowledge of the physiology of digestion. The lectures were given in connection with the celebration of the publication of Beaumont's book on this subject.

Differentialdiagnose in der Inneren Medizin. Lieferung 2. Von Prof. Dr. Med. O. Naegeli, Direktor der Medizinischen Universitätsklinik, Zürich. Paper. Price, 9.60 marks. Pp. 217-414, with 42 illustrations. Leipzig: Georg Thieme, 1936.

This volume of Naegeli's differential diagnosis continues the same high quality of condensed discussion that was present in the first volume reviewed in THE JOURNAL, July 11, 1936, page 156. The present volume includes presentation of the differential diagnosis of diseases of the abdomen, lungs and pleura. Diseases of the abdomen are divided into (1) abdominal pain, (2) abdominal resistance, (3) inflammatory lesions, (4) stenoses of the gastro-intestinal tract, (5) gastric diseases (ulcer, carcinoma and gastritis), (6) constitutional disorders, (7) rare gastric disorders, (8) achylia, (9) appendicitis, (10)

the peritonitides, (11) diseases of the bowel and (12) diseases of the pancreas. The discussion of gastric disease receives disproportionate emphasis (thirty-four pages); all the rest of the gastro-intestinal tract is treated in but eighteen pages. The discussion of pulmonary tuberculosis is the least impressive portion of the work. Naegeli writes well and emphatically, but one again receives the impression that the patient is considered as a loosely correlated collection of systems rather than a finely correlated whole. The volume can be recommended as a reference work revealing modern European thought and methods.

The Truth About Bright's Disease. By William R. Ohler, M.D. Cloth. Price, \$1. Pp. 80, with one illustration. Cambridge: Harvard University Press, 1936.

This little book, which can easily be read in an hour, presents the substance of a popular lecture recently delivered at the Harvard Medical School. Since the book is intended for laymen, its language is not technical. It should prove instructive to intelligent patients who have nephritis, or to parents of afflicted children. Dr. Ohler considers only the common forms of "Bright's disease": that attributable to inflammation or to bacterial invasion, and that attributable to degeneration or sclerosis of small arteries. Comments are made on the structure and function of the kidneys, the nature of normal and abnormal urine, the scope of Bright's disease and its course, and uremic poisoning and dropsy. Also briefly discussed are diet and dietary management, Bright's disease in pregnancy, and the treatment of acute and chronic nephritis.

The Aims and Methods of Medical Science: An Inaugural Lecture. By John A. Ryle, M.A., M.D., F.R.C.P., Regius Professor of Physic in the University of Cambridge. Paper. Price, 75 cents; 2s. Pp. 44. New York: Macmillan Company; Cambridge: The University Press, 1935.

This little brochure contains the lecture delivered by John A. Ryle on the occasion of his inauguration as regius professor of physic in the University of Cambridge. It is a scholarly discussion, with some criticism and some forecast of the ever present and ever important topic announced by the title. Professor Ryle is well aware of the value of research by specialists who devote all their time to the laboratory or ward. It is not surprising, however, that he who for many years has been in active practice in the hospital and the home should contend for the worth also of scientific observation by the one whose primary function is that of the practitioner. The ideas of the lecture are the same as those expressed in his larger publication, *The Natural History of Disease*, which was reviewed in THE JOURNAL Sept. 5, 1936.

Wall Chart and Code for Lungs Examination. By H. N. Chatterjee, B.Sc., M.D. Paper. Price, 2s.; Re. 1/8. Calcutta: Thacker Spink & Co., Ltd., 1933.

This wall chart, 13 by 17 inches in size, is a handy outline for chest clinics. It lists the apparatus needed for lung and throat examinations and then describes the position of the patient. There is a brief description of abnormalities observed on inspection, detection of abnormalities on palpation, sounds on percussion, and auscultatory sounds. In the center of the chart is presented a code of markings for the chest specialist, including auscultation and percussion signs. The chart is a useful guide for training physicians in the systematic and thorough examination of the lungs.

The Diagnosis and Treatment of Pneumonia. By Campbell P. Howard, B.A., M.D., C.M., Physician to the Montreal General Hospital, Montreal, Canada. Henry A. Christian, M.D., Sc.D., LL.D., General Editor of the Series. [Reprinted from Oxford Monographs on Diagnosis and Treatment.] Cloth. Price, \$6.50. Pp. 373. New York: Oxford University Press, 1936.

This reprint from the Oxford Monographs on the diagnosis and treatment of pneumonia is a valuable compendium of the literature and contains chapters on the history, incidence and etiology, infection and immunity, morbid anatomy, symptomatology, physical signs, complications, clinical types and diagnosis, prognosis, prophylaxis and treatment of lobar pneumonia. There is a chapter on bronchopneumonia and one on the common cold. The latter contains some of the more recent work on the virus. The bibliography is excellent. A survey of our present knowledge of pneumonia may be found in this volume.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Societies: Contract Practice in Relation to Professional Ethics.—The plaintiffs, one as its manager, were employed by the Associated Physicians Clinic, operated by two members of the King County Medical Society. This clinic made contracts with business firms of Seattle to furnish necessary medical, surgical and hospital care to employees of such firms at a stipulated rate per month per capita. In April 1933 the King County Medical Society organized the King County Medical Service Corporation, described in the record as "identical in its plan and operation with that of the Associated Physicians Clinic and the other independent clinics." The following August, the medical society adopted an amendment to its by-laws, providing for the censure, suspension or expulsion of a member—

who shall engage in contract practice unless the same shall previously have been authorized by the Board of Trustees of this Society, or who as physician or surgeon shall serve on the staff of or perform work for the patients of, or shall perform work in any institution or group or organization unless such services or work shall previously have been authorized by the Board of Trustees of this Society.

Shortly thereafter the society, it was alleged, threatened to expel the physicians who operated the Associated Physicians Clinic unless they abandoned their contract practice. The physicians apparently continued to engage in contract practice and on March 19, 1934, written charges were filed with the society against them, charging a violation of the by-law quoted. The two physicians then terminated their contracts with the plaintiffs, who thereupon instituted the present suit against the King County Medical Society, the King County Medical Service Corporation and certain officers, trustees and members thereof, alleging that the defendants had caused a breach of the contract between the Associated Physicians Clinic and the plaintiffs. The trial court sustained a demurrer interposed by the defendants, on the ground that the complaint failed to state a cause of action, and the plaintiffs appealed to the Supreme Court of Washington.

An employee, said the Supreme Court, has no right of action against an individual or group of individuals who organize to compete with his employer. The organization of the King County Medical Service Corporation by the King County Medical Society as a competitor of the Associated Physicians Clinic, therefore, did not create a cause of action against the defendants. Furthermore, the constitution, charter and by-laws of the medical society constituted a contract between the members of the society enforceable in the courts if not immoral or contrary to public policy or the law of the land. The two physicians, as members of the medical society, were required to obey the by-laws of the society or subject themselves to the penalty of suspension or expulsion from the society, and it is not material how selfish or unselfish the objects of the medical society may be. That the medical society had the right to adopt the by-law with respect to contract practice cannot be questioned. Whether such by-law was just, reasonable or wise is a question of policy which concerns only the medical society and its members. The society, in the enforcement of its by-laws for the direct purpose of benefit to itself and to its members, is not answerable for damage incidentally resulting to a third person. So long as membership in the medical society continues, the member can be compelled under his contract with the society to obey its laws, rules and regulations or suffer the penalty of fine, suspension or expulsion.

The enforcement of a by-law such as the one here involved, continued the court, does not amount to unlawful coercion. In *Seymour Ruff & Sons, Inc. v. Bricklayers', etc., Union*, 163 Md. 687, 164 A. 752, it was said:

The decisions are practically in harmony in holding that it is within the power of labor unions, and it is lawful for them, to instruct or order their members not to accept employment with an individual, or to continue in such person's employment, where the action of a union is justifiable in the

sense that it is to promote the welfare of the members of the union. Accordingly, the enforcing of a by-law forbidding members of the union to serve one who has broken a contract with its members does not amount to intimidation. Neither a fine or other disciplinary action under such by-law would be unlawful as to members who voluntarily subject themselves to the provision of such by-law. They are left free to enter the employment of the prescribed employer, although practically they are compelled to choose between the benefits of such employment and membership in the union.

In *Booker & Kinnaird v. Louisville Board of Fire Underwriters*, 118 Ky. 771, 224 S. W. 451, 21 A. L. R. 531, the court said:

In almost every profession and every business there are associations or lodges or boards, organized by persons engaged in particular lines of industry or following certain professions, that have for their sole purpose the protection and promotion of the best interest of the business or profession in which they are engaged. And bodies like these, acting in a collective capacity, may, in a quiet orderly way when their interests demand it, refuse to deal with or have any business relations with any other person or persons they choose, although the effect of such combined action is to boycott the objectionable person. . . .

An association, in pursuing its legitimate objects, has the right to coerce a member by fine, suspension or expulsion, and the association will not, nor will its members, be liable in damages to those who may be directly or indirectly injured by such efforts. So long as a member remains in the association, he is subject to the coercive effect of a penalty exacted for breach of a by-law of the association. If he does not desire to abide by the obligations of his contract of membership, he may abandon his membership. No rights of the plaintiffs in this case, who were nonmembers, were invaded by the medical society when it established its code of ethics and insisted on compliance therewith through threat of expulsion of an offending member, and the enforcement of solidarity by threat of expulsion of the two physicians created no cause of action for the incidental damage resulting to the plaintiffs.

The judgment of the trial court for the defendants was therefore affirmed.—*Porter et al. v. King County Medical Society et al.* (Wash.), 58 P. (2d) 367.

Medical Practice Acts: Practice of Medicine by Insurance Company.—The Benjamin Franklin Life Assurance Company submitted to the state insurance commissioner of California for approval an insurance policy indemnifying against loss by reason of medical and hospital expenses occasioned by disease or injury suffered by the insured. The policy provided that the insurance company would reimburse the insured for actual expenditures made or obligations incurred for services rendered by legally qualified physicians, optometrists, hospitals, ambulances, pharmacies and x-ray medical laboratories, "approved and designated by the Policy-Holders Committee of the Company for the benefit of the Insured." In the application for the policy, the applicant authorized the policyholders committee "to approve and designate for me, during the life of the policy, the renderers of the services under the terms of the policy for which I am applying." The policy further provided that if the insured placed himself under the treatment or care of any person other than those approved and designated by the committee he thereby forfeited any rights to reimbursement for expenses in connection with such treatment or care. The insurance commissioner refused to approve the policy, and the company instituted mandamus proceedings to compel approval. The trial court gave judgment for the insurance company, and the insurance commissioner appealed to the district court of appeal, second district, division 1, California.

The insurance commissioner contended that the policy violated the medical practice act of California and that he should not be compelled to approve a policy the terms of which were unlawful. The court called attention to the fact that neither a corporation nor any other unlicensed person or entity may engage, directly or indirectly, in the practice of medicine. The insurance company urged that the policy did not undertake or agree to furnish any medical or other services to its members, nor undertake to employ any one to furnish such services, nor undertake to pay compensation to any person who furnished medical or other services. At the most, it was contended, the policy undertook to reimburse a policyholder the cost and

expenses incurred by him for medical and other services designated in the policy and such reimbursement was payable directly to the policyholder himself. While all this is literally true, the court said, that which the company as such cannot lawfully do it requires its members, by means of a contract with such members as individuals, to accomplish for it through the medium of a so-called policyholders committee, which in fact is not a committee of the policyholders but a committee of the company. The selection and designation of physicians by this committee is therefore a selection and designation by the company. The company thereby undertakes to do indirectly what it cannot do directly. If in its inception, said the court, it was not the plan of the company to circumvent the medical practice act, it is a coincidence that the physicians designated by the committee were to be so well protected, for in that connection the policy does not provide that the insured shall be compensated for losses covered by the policy, but that the insured shall be reimbursed. In other words, the insured is to get nothing until the physician is paid. The policyholder is not accorded the privilege of presenting his claim, collecting the amount and then paying the doctor. Under such circumstances it is evident that the physicians to be designated by the committee of the company are to receive equal, if not first, consideration in the dispensing of benefits. The company's plan, although designated insurance, plainly provides for the sale of medical services, which is the practice of medicine. The contention of the insurance commissioner, therefore, that the company under the guise of an insurance company proposed to engage in the practice of medicine must be sustained. The judgment of the trial court for the company was therefore reversed.—*Benjamin Franklin Life Assur. Co. v. Mitchell, Insurance Com'r (Calif.)*, 58 P. (2d) 984.

Physical Examinations: Examining Physician Appointed by Court; Scope of Examination.—A Florida statute authorizes the court to appoint a physician to examine the plaintiff in a personal injury action when requested to do so by the defendant. The statute, said the Supreme Court of Florida, contemplates any and every kind of physical examination or test that may be deemed necessary or essential to ascertain the physical condition of the person examined. Even in the absence of statute, courts have inherent power to order a physical examination of the plaintiff in personal injury cases by a competent physician when such an examination is necessary to ascertain the nature, extent or permanence of the injuries. If the appointed physician determines that a microscopic or bacteriologic examination is necessary, and he cannot make such examination himself, he may have it made by a competent technician, pathologist or toxicologist or by another physician. He may send specimens to adequately equipped laboratories.

The report, however, of a chemist, bacteriologist or laboratory technician as to the result of his examination is not admissible in evidence. The person who made the examination, if he is qualified as an expert, may testify as to what it showed. A witness may qualify as an expert who is shown to have sufficient knowledge, whether gained from books, experience or experiments or other reliable sources, to make his opinion of value, and the trial court is vested with discretion in determining when such knowledge is exhibited. A physician appointed by a court cannot testify as to the nature and extent of an injury based solely on the report of an examination made to him by a technician or pathologist. The technician or pathologist must first testify as to the result of the examination and the physician may predicate his opinion on such testimony.—*Deffer v. Walker (Fla.)*, 168 So. 810.

Workmen's Compensation Acts: Compensability of Asbestosis.—Where the evidence shows, said the Supreme Court of North Carolina, that an employee is suffering from asbestosis arising out of and in the course of employment and that such disease was not caused by accident, the injury results from an occupational disease and compensation under the workmen's compensation act was properly denied by the industrial commission.—*Savink v. Carolina Asbestos Co. (N. C.)*, 186 S. E. 258.

Society Proceedings

COMING MEETINGS

- Alabama, Medical Association of the State of, Birmingham, April 20-22. Dr. D. L. Cannon, 519 Dexter Ave., Montgomery, Secretary.
- American Association for the Study of Neoplastic Diseases, Philadelphia, April 9-10. Dr. E. R. Whitmore, 2139 Wyoming Ave. N.W., Washington, D. C., Secretary.
- American Association on Mental Deficiency, Atlantic City, N. J., May 5-8. Dr. E. Arthur Whitney, Elwyn, Pa., Secretary.
- American College of Physicians, St. Louis, April 19-23. Mr. E. R. Loveland, 4200 Pine St., Philadelphia, Executive Secretary.
- American Otolological Society, New York, May 27-28. Dr. Thomas J. Harris, 104 East 40th St., New York, Secretary.
- American Pediatric Society, University, Va., April 29-May 1. Dr. Hugh McCulloch, 325 North Euclid Ave., St. Louis, Secretary.
- American Physiological Society, Memphis, Tenn., April 21-24. Dr. A. C. Ivy, 303 East Chicago Ave., Chicago, Secretary.
- American Psychiatric Association, Pittsburgh, May 10-14. Dr. William C. Sandy, State Education Bldg., Harrisburg, Pa., Secretary.
- American Society for Clinical Investigation, Atlantic City, N. J., May 3. Dr. J. M. Hayman Jr., 2065 Adelbert Road, Cleveland, Secretary.
- American Society for Experimental Pathology, Memphis, Tenn., April 21-24. Dr. Shields Warren, 195 Pilgrim Road, Boston, Secretary.
- American Society for Pharmacology and Experimental Therapeutics, Memphis, Tenn., April 21-24. Dr. E. M. K. Geiling, 947 East 58th St., Chicago, Secretary.
- American Society of Biological Chemistry, Memphis, Tenn., April 21-24. Dr. H. A. Mattill, Chemistry Building, State University of Iowa, Iowa City, Secretary.
- Arizona State Medical Association, Yuma, April 1-3. Dr. D. F. Harbridge, 15 East Monroe St., Phoenix, Secretary.
- Arkansas Medical Society, Little Rock, April 12-14. Dr. W. R. Brooksher, 602 Garrison Ave., Ft. Smith, Secretary.
- Association of American Physicians, Atlantic City, N. J., May 4-5. Dr. Hugh J. Morgan, Vanderbilt University Hospital, Nashville, Tenn., Secretary.
- California Medical Association, Del Monte, May 2-5. Dr. F. C. Warnshuis, 450 Sutter St., San Francisco, Secretary.
- Connecticut State Medical Society, Bridgeport, May 19-20. Dr. Creighton Barker, 258 Church St., New Haven, Secretary.
- District of Columbia, Medical Society of the, Washington, May 5-6. Dr. C. B. Conklin, 1718 M St. N.W., Washington, Secretary.
- Federation of American Societies for Experimental Biology, Memphis, Tenn., April 21-24. Dr. Shields Warren, 195 Pilgrim Road, Boston, Secretary.
- Florida Medical Association, St. Petersburg, April 5-7. Dr. Shaler Richardson, 111 West Adams St., Jacksonville, Secretary.
- Georgia, Medical Association of, Macon, May 11-14. Dr. Edgar D. Shanks, 478 Peachtree St. N.E., Atlanta, Secretary.
- Hawaii Territorial Medical Association, Hilo, April 30-May 2. Dr. Douglas B. Bell, Queen's Hospital, Honolulu, Secretary.
- Illinois State Medical Society, Peoria, May 18-20. Dr. Harold M. Camp, 202 Lahl Bldg., Monmouth, Secretary.
- Iowa State Medical Society, Sioux City, May 12-14. Dr. Robert L. Parker, 3510 Sixth Avenue, Des Moines, Secretary.
- Kansas Medical Society, Topeka, May 3-6. Mr. Clarence G. Munns, Stormont Bldg., Topeka, Executive Secretary.
- Louisiana State Medical Society, Monroe, April 26-28. Dr. P. T. Talbot, 1430 Tulane Ave., New Orleans, Secretary.
- Maryland, Medical and Chirurgical Faculty of, Baltimore, April 27-28. Dr. Walter Dent Wise, 1211 Cathedral St., Baltimore, Secretary.
- Medical Library Association, Richmond, Va., May 23-26. Miss Janet Doe, 2 East 103d St., New York, Secretary.
- Minnesota State Medical Association, St. Paul, May 3-5. Dr. E. A. Meyerding, 11 West Summit Ave., St. Paul, Secretary.
- Mississippi State Medical Association, Meridian, May 11-13. Dr. T. M. Dye, McWilliams Bldg., Clarksdale, Secretary.
- Missouri State Medical Association, Cape Girardeau, May 10-12. Dr. E. J. Goodwin, 634 North Grand Blvd., St. Louis, Secretary.
- Nebraska State Medical Association, Omaha, May 11-13. Dr. R. B. Adams, 15 N Street, Lincoln, Secretary.
- New Hampshire Medical Society, Manchester, May 18-19. Dr. Carleton R. Metcalf, 5 South State St., Concord, Secretary.
- New Jersey, Medical Society of, Atlantic City, April 27-29. Dr. J. B. Morrison, 66 Milford Ave., Newark, Secretary.
- New York, Medical Society of the State of, Rochester, May 24-26. Dr. Peter Irving, 2 East 103d St., New York, Secretary.
- North Carolina, Medical Society of the State of, Winston-Salem, May 3-5. Dr. L. B. McBrayer, Southern Pines, Secretary.
- North Dakota State Medical Association, Grand Forks, May 16-18. Dr. Albert W. Skelsey, 20½ North Broadway, Fargo, Secretary.
- Ohio State Medical Association, Dayton, April 28-29. Mr. C. S. Nelson, 79 East State St., Columbus, Executive Secretary.
- Oklahoma State Medical Association, Tulsa, May 10-12. Dr. L. S. Willour, 203 Ainsworth Bldg., McAlester, Secretary.
- Society for the Study of Asthma and Allied Conditions, Atlantic City, N. J., May 1. Dr. W. C. Spain, 116 East 53d St., New York, Secretary.
- South Carolina Medical Association, Columbia, April 13-15. Dr. E. A. Hines, Seneca, Secretary.
- South Dakota State Medical Association, Rapid City, May 24-26. Dr. John F. D. Cook, Langford, Secretary.
- Tennessee State Medical Association, Knoxville, April 13-15. Dr. H. H. Shoulters, 706 Church St., Nashville, Secretary.
- Texas, State Medical Association of, Fort Worth, May 10-13. Dr. Holman Taylor, 1404 West El Paso St., Fort Worth, Secretary.
- Western Branch of American Public Health Association, Phoenix, Ariz., April 13-15. Dr. William P. Shepard, 600 Stockton St., San Francisco, Secretary.
- West Virginia State Medical Association, Clarksburg, May 24-26. Mr. Joe W. Savage, Public Library Bldg., Charleston, Executive Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Alabama Medical Association Journal, Montgomery

6: 257-292 (Feb.) 1937

- Factors in Automobile Accidents: Fatigue, Disease and Alcoholic Beverages. S. Harris, Birmingham.—p. 257.
Hypertension Without Edema. P. Clayton, Russellville.—p. 265.
Some Points in Differential Diagnosis of Common Lung Diseases. C. Lull, Birmingham.—p. 267.
Practical Suggestions in Pediatrics. J. J. Repa, Montgomery.—p. 270.

American Heart Journal, St. Louis

13: 129-256 (Feb.) 1937

Variations in Electrocardiographic Form of Experimental Ventricular Ectopic Beats Induced in Monkey and Dog. D. I. Abramson, Brooklyn; L. N. Katz, Chicago; S. Margolin, New York, and R. Lourie, Brooklyn.—p. 217.
Displacement of Esophagus by Cardiac Lesions Other Than Mitral Stenosis. A. Babey, Brooklyn.—p. 228.

Electrocardiographic Changes in Normal Adults Following Administration of Digitalis.—Larsen and his associates investigated the effect of therapeutic doses of digitalis in fifteen normal young adults on each of the different parts of the electrocardiogram. A relative shortening of the QT interval was observed after administration of digitalis. This is in agreement with the demonstration by Wiggers and Stimson of a shortening of the systole following the administration of strophanthin to vagotomized dogs, whose heart rate was kept constant through electrical stimulation of the atrium. The changes in the height of the T waves are not in agreement with the observations of other investigators. The T waves became lower in one or more leads in fourteen cases and remained unchanged in one. The other changes in the electrocardiogram observed were found in only a few individuals. The heart rate became slower in nine and the conduction time increased in four cases. In two of the latter cases the PQ interval was above 0.2 second and the length of the interval varied with the respiratory phase. Therefore the conclusion is drawn that different individuals may behave differently toward the same dose of digitalis. The electrocardiographic changes were found to persist up to a period of about one month, a fact that must be considered in interpretation of electrocardiograms from patients who have received digitalis. Electrocardiographic changes were noticed, at the earliest, two hours after ingestion of the digitalis.

Heart Disease Among Seamen.—Arenberg points out that of about a million alien seamen entering and leaving the ports of the United States yearly one half pass through the port of New York. Heart disease is the leading cause of death among seamen, as it is among other groups of the population. Of 485 cases of heart disease, including fifty necropsies, selected from more than 5,000 seamen patients who had been subjected to a special cardiovascular examination regardless of the ailments for which they were admitted to the hospital, forty-five

were not Caucasian. About 41 per cent of the group were native Americans, representing almost every state in the Union, and 59 per cent were foreign, coming from all parts of the world. Of the 485 patients, 130 had active or latent syphilis; 44 per cent of these had cardiovascular syphilis. The hypertensive group was the largest, totaling 202 patients. Their age extremes were 29 and 76 years, with the greatest number in the fifth and sixth decades of life. In the rheumatic group there were 102 cases. Only a small number were from the tropical or subtropical regions, while fifty of fifty-six Americans were from the Northeastern states. Sixty-nine had histories of rheumatic fever, and eleven histories of chorea. The age extremes were 19 and 62 years, the greatest number being in the third and fourth decades of life. There were twenty-seven asymptomatic patients in this group, and twenty-one had latent or active syphilis, while twenty-three had auricular fibrillation. In the atherosclerotic group were included all cases of coronary disease, coronary thrombosis, myocardial damage, sclerosis of the aortic valve and nonsyphilitic aneurysm, of which there were eighty-eight. The tropical and subtropical countries were almost entirely unrepresented. The age extremes were 37 and 75 years. The greatest number of cases occurred in the sixth and seventh decades. In contrast to the other groups there were only twelve asymptomatic cases. There were fifty-seven patients in the cardiovascular syphilitic group, fifty-five of whom had positive serologic reactions and two of whom had histories of syphilis with negative reactions. There were eleven asymptomatic cases. The age extremes were 26 and 68 years. There were eight patients with aneurysm, only two of whom gave a history of antisyphilitic treatment prior to this observation. The miscellaneous group of thirty-six cases included aortic insufficiency, auricular fibrillation, congenital cardiac lesions, adherent pericarditis, bacterial endocarditis, chronic cor pulmonale, thyroid heart conditions and cardiac hypertrophy of undetermined cause. Hypertension seems to be more frequent among seamen than among other groups in New York, and less frequent than it is in the Northwest. Rheumatic heart disease is about as frequent as among the general population, but American seamen are apparently more susceptible to it than seamen from other countries. The frequency of cardiovascular syphilis among seamen is from two to three times as great as that among adult males of the general population.

Efficiency of State and Local Laboratories in Performance of Serodiagnostic Tests for Syphilis.—Parran states that the study of the committee on the evaluation of serodiagnostic tests for syphilis reveals that in some of the state and local laboratories the serologic testing does not compare

favorably with the results achieved in the laboratories of the originators of the methods. On the other hand, in other state and local laboratories the results achieved are at least comparable to those obtained with the control tests. An efficient serodiagnostic test for syphilis should possess specificity of 100 per cent. Any test that yields even 1 per cent of false positive reactions should be so modified as to increase its specificity, even with some slight sacrifice of sensitivity. The examination of the clinical records of the presumably syphilitic donors in this study again emphasizes the fact that a serologic diagnosis of syphilis unsupported by history or clinical evidence should never be made on the basis of a single positive blood reaction. If a positive blood test is obtained in a person who presents no history or clinical evidence of syphilis, the test should be repeated in the same laboratory or in another laboratory, two or more different tests being utilized. The studies made by this committee show that, if two tests are to be performed, it is immaterial whether two efficient complement fixation tests, two efficient flocculation tests or a combination of one efficient flocculation test and one efficient complement fixation test is selected. It is satisfactory to report the results of qualitative tests as merely positive, doubtful or negative. In this way the confusion arising from the use of various symbols is avoided. The directors of laboratories performing serodiagnostic tests for syphilis should have, and should avail themselves of, the opportunity of comparing their results with those of well qualified serologists in other laboratories performing the same test on comparable samples from known syphilitic and presumably nonsyphilitic individuals. The committee recommends that such a system of comparative examination of tests be extended annually to all state laboratories. In turn, the state laboratories should offer a similar opportunity to local laboratories.

*Intestinal Stasis Due to Low Mineral Intake. Elizabeth Chant Robertson, Toronto.—p. 500.
Myringitis Bullosa Haemorrhagica. S. Karelitz, New York.—p. 510.

Reaction Following Intramuscular Injection of Whole Blood.—Of a group of 1,341 children given injections of citrated whole blood intramuscularly, fifty-two showed fever, malaise and leukocytosis, with swelling, redness and pain at the sites of injection for from two to ten days, average five and seven-tenths days, after the injection. These symptoms lasted from two to seven days (average three and one-half days) and left no sequels. Rapoport and Stokes investigated the blood types of seventeen of the children and the donors. All showed that their serum agglutinated the cells of the donor. It cannot be concluded that incompatibility of a recipient's serum with a donor's cells will always lead to a reaction following the intramuscular injection of blood. Surely more than fifty-two such incompatibilities would have occurred in a group of 1,341 injections, and what is more conclusive, the blood of some of the brothers and sisters of reacting children was similarly incompatible with that of their donors and they did not show reactions. Thirteen of the seventeen children showed hemolysis in their serum against the corpuscles of their donors. While no titrations of this hemolysis were attempted, it appeared to be present in fairly high titer, because in all instances the hemolysis took place before agglutination could occur. The hemolysins present in the serums of these thirteen children were probably an increase of normally occurring isohemolysins, in response to the injection of incompatible blood corpuscles. The other four children may have been tested too long after their reaction for hemolysis to take place, as the others were done within four weeks after the reaction.

Intestinal Stasis Due to Low Mineral Intake.—About two years ago, in the course of some other experiments, Robertson observed that rats fed a diet low in minerals showed intestinal stasis, which is evidenced by dilatation and overloading of the large intestine and by much delayed excretion of carmine and barium. The stasis can be cured by adding the missing minerals. Since the addition of calcium and potassium will prevent stasis, it seemed possible that a deficiency of these elements might cause stasis and it was decided to try out the effect of a diet containing about 0.2 Gm. of calcium and about 1 Gm. of potassium daily on nineteen convalescent children from 7 to 12 years of age, the intake of these minerals being reduced to about one fifth of the commonly accepted optimum. The tests on children are not completed, but they suggest that diets low in calcium and potassium are constipating and that such diets low in ash may cause stasis in the appendix which might easily increase the chances of formation of fecaliths and infection. When given a barium sulfate meal, 33 per cent of eighteen children fed diets low in calcium and potassium retained the barium in the appendix for from four to twenty-one days. The same children when fed normal diets did not show barium in the appendix for more than one day.

Experience with Picric Acid-Alum Spray in Prevention of Poliomyelitis in Alabama.—Armstrong states that the appearance of poliomyelitis in Alabama in 1936 afforded an opportunity to carry a field trial on man of spraying the nasal passages. In order to determine the extent to which the spray had been used, a house-to-house survey was carried out in twenty representative districts of Birmingham and in seven of Jefferson County. A total of 2,076 families composed of 8,093 inmates were thus canvassed, of whom 5,010, or 61.9 per cent, were sprayed at some time between July 15 and August 22. From a total of 5,097 white people there were 3,545, or 69.7 per cent, who had been sprayed, while of 2,996 colored people 1,465, or 48.9 per cent, had employed the chemicals. Assuming the same rate of spraying for the whole area, it appears that the sprayed and not sprayed groups dealt with approximated 270,000 and 160,000 individuals, respectively. The very young and the older adults sprayed less than the more susceptible age group. Records as to the effects of the chemicals were secured from 4,631 individuals in the Birmingham area who had sprayed from

one to eight or more times. In 3,758 of these there was no complaint, while 885 complained of uncomfortable but not serious conditions, such as headache for from one to thirty-six hours; nausea, usually after the first or second applications; temporary burning of the nose; head colds, and irritation of the nose or eyes. Calculations were confined to paralytic cases, of which sixty-seven were reported from the Birmingham area from June 6 to September 26. Whether the results would have been better had the spraying been carried out more effectively is unknown. The development of poliomyelitis among persons apparently sprayed according to instructions, however, suggests either that the chemicals are not effective for man or that the suggested method of application, which Peet and Schultz have shown effective for monkeys, was not, as practiced, trustworthy for man. The apparent, though small, reduction in the expected number of sprayed patients suggests the latter alternative, and it is possible that the greater nasal distances and larger surfaces to be covered in children are important considerations. The best method for applying the chemicals evidently was not employed in all the prophylactic failures encountered, and it is furthermore probable that the most satisfactory solution has not yet been found. The actual incidence of poliomyelitis in the group sprayed by whatever method was somewhat less than the calculated incidence based on the rate in the unsprayed control group (16:21.7) (Birmingham area).

Thoracopagus.—Sangvichien observed a female thoracopagus joined together from the suprasternal notch to the umbilicus. The umbilical cord was single but appeared as the fusion of two cords; at the placental end they were separated for a distance of 40 mm. with amnion left between. The peculiarity of this monster was that one of the twins had harelip and cleft palate, while the other had a normally developed face. The deformity appeared on the left side of the face; the nostril of that side was deformed by the forward and medial inclination of the left medial incisor. When the abdomen was opened the livers were found joined together. From measurement the twins were nearly equal in size and neither could be called the parasite of the other.

Studies on Intoxication with Vitamin D.—With the extensive application of massive doses of vitamin D as a therapeutic agent in various clinical conditions, numerous criticisms have arisen which Steck and his associates have summarized as follows: 1. Hypervitaminosis D may produce symptoms of hyperparathyroidism. 2. The therapeutic use of vitamin D is rational only in conditions of known deficiency. 3. Animals experimentally treated with vitamin D concentrates have shown extensive calcium deposits in various tissues, and other pathologic changes have been found. There is, thus, danger of permanent injury to human subjects. Observations on sixty-four dogs and 773 human subjects receiving massive doses of vitamin D have been made and data recorded as to dose per unit of body weight, and on the nature of the process of intoxication. Both human subjects and dogs generally survive the daily administration of 20,000 units per kilogram for indefinite periods without intoxication. Hypervitaminosis D first produces cell injury followed by calcium deposition. This process is reversible and repairable if administration is discontinued promptly, but neither animal nor human subjects in the authors' experience have ever recovered from the toxic condition while administration continued.

Dietetic Treatment of Constipation.—Kantor and Cooper suggest that the diet for constipation should be planned with the same precision as that for diabetes or obesity. In other words the physician should be able to think in quantitative terms about fiber as he does about calories, carbohydrates, fats or proteins. Cowgill's concept of the physiologic fiber minimum should receive due recognition. The fiber content of the more important fruits, vegetables and cereals should be made more generally available to the physician. According to the Cowgill standard of 100 mg. of fiber per kilogram of body weight, a man of 154 pounds (70 Kg.) will normally require 7 Gm. of fiber daily; a woman of 121 pounds (55 Kg.) will need 5.5 Gm. In order to obtain this total, selection may be made in approximately equal portions from each of the three classes of fibrous foodstuffs—fruits, vegetables and cereals. Only bland foods should be selected at the beginning of treatment. 1. From the list of fruits, three varieties may be chosen, preferably one for each meal. Assuming that apples, prunes and bananas are taken, it will be noted that the fiber in three average portions adds up to 2.2 Gm. 2. Four vegetables should be selected, including one serving of potato (0.4 Gm.). If to this are added string beans (1.05 Gm.), spinach (0.45 Gm.) and asparagus (0.35 Gm.), the total from this source becomes 2.25 Gm. 3. For the cereal foodstuffs one whole grain cereal, such as shredded wheat (0.78 Gm.), with perhaps a slice of whole wheat bread (0.36 Gm.), should be taken for breakfast. At each of the other two meals, two slices of bread (0.72 Gm.) may be used. This brings up the total for this group to 2.58 Gm. Other cereal products, such as noodles, cake, pastry and certain puddings, may be substituted for some of the bread. Every effort should be made to avoid colic, distention and other evidences of irritation, since the resulting spasm may serve to increase the fecal stasis. In any regimen for the treatment of constipation, adequate water intake is essential to supply the means by which the fruit and vegetable pectins and galactans soften the feces. The discovery of an active principle in prunes suggests that certain fruits may possess special cathartic properties in addition to their fiber-acid-sugar content.

However, the authors' experiment fails to show unmistakable superiority for prunes, because only five of their nine subjects rated them first in laxation and two reported them least effective as compared with apples and bananas. Cooked apples may be substituted for the raw. Bananas may be served in any way desired, but if eaten raw they must be ripe, since the unconverted starch may cause "indigestion."

Vesiculobullous Dermatitis Following Administration of Arsphenamine.—In Muir's case of vesiculobullous dermatitis following the administration of arsphenamine the initial erythema appeared on the ninth day of arsphenamine therapy suggesting that the eruption may have been the "erythema of the ninth day," although its duration was somewhat longer than usual. A severe neuritis developed during the course of the erythema, and about a week later an unusually severe vesiculobullous eruption ensued. The neuritis can in all probability be interpreted as due to arsphenamine, but its association with subsequent vesicular dermatitis suggests a connection between the two. It is unusual to see an eruption associated with arsenical neuritis; so in all probability the dermatitis in this case should be considered toxic and a manifestation of the general arsphenamine intoxication, as dermatitis may be caused by toxic substances formed elsewhere; for instance, in the liver. The point of action of the toxin on the skin may have been either the epidermis or the dermis. The influence of focal infection on the development of arsenical dermatitis has been discussed by others. The patient had had salpingo-oophoritis followed a year later by acute gonorrheal salpingitis. During the following year she had chronic iridocyclitis of undetermined origin. In addition to her infections she had also had functional colitis, which indicates a background of neurocirculatory instability, a condition predisposing to sensitization. Death was evidently due to the general toxic degeneration of the vital organs, presumably of arsenical origin, but evidences of infection (pleural abscess and fibrinous peritonitis) suggest that an infectious complication was present.

Acneform Dermatitis Produced by Orthochlorphenol Sodium and Tetrachlorophenol Sodium.—Butler has observed twenty-one cases of an acneform eruption which occurred in persons handling a mixture of ortho (2 chlorophenyl) phenol sodium and tetrachlorophenol sodium. Only persons handling the finished products were affected. These men did not handle or come in contact with any by-products. Other men working in the same building but not coming into direct contact with the agents remained unaffected. In some patients the disorder developed several months after exposure had ceased. The essential lesions were predominantly papulofollicular and were associated with marked hyperkeratosis. Enormous numbers of comedones and numerous sebaceous cysts were present. Secondary pustular lesions from the size of a pea to that of a chestnut were observed. The eruption began with a few papules behind the ears; then it spread to the forehead, cheeks, chin and back of the neck. The scalp, hands and feet were not affected. No reactions occurred in persons who had not been exposed to the chemicals concerned. Patch tests failed to show any epidermal sensitization. Roentgen therapy proved helpful but not cura-

tive. These drugs should not be used as fungicidal agents until further investigation reveals the mechanism whereby they produce this dermatosis. The author is of the opinion that a constitutional reaction is involved.

Recklinghausen's Neurofibromatosis.—During the last three years, Sharpe and Young have observed thirty-one patients with Recklinghausen's neurofibromatosis. They propose to demonstrate examples of the multiple manifestations of the condition and to emphasize the influence of various physiologic factors and life experiences on the disease. It is suggested that from a congenital or inherited mesodermal abnormality an embryonic tissue arrest is formed, which at birth or during infancy, childhood, puberty or pregnancy may become clinically manifest, depending on its response to the stimulation of the normal physiologic growth factor. This reaction to the influence of physiologic factors and life experiences leads to the progressive and changeable course of the disease. The clinical features that any particular patient may present will be dependent on his age, the congenital factors and his individual sensitivity to stimulating influences. Of all the influences studied in the thirty-one cases, pregnancy produced the most stimulative effect in the progressive course of the disease. Avoidance of pregnancy affords the chief opportunity for control and arrest, as the disease in a large percentage of cases is hereditary and is without beneficial treatment. It is hoped that further attention to the history of the disease during the life of affected subjects, rather than a consideration of the more classic, static, nosologic cross-section of the disease that the patients present at any life period, will be productive of a more helpful management.

Neurologic Manifestations in Vitamin G Deficiency.—The basal diet that Zimmerman and his associates employed in their study consisted of an artificially balanced ration which was palatable to the dog and adequate in all known dietary essentials except water-soluble, heat-stable vitamin G (B₂). The experiment was controlled by feeding a second group of dogs the same diet plus 0.1 Gm. of liver extract per kilogram of body weight daily. A third group of animals served as controls for

the inanition factor; each animal was fed daily only as much of the basal ration as his experimental partner had eaten on the preceding day and an adequate amount of vitamin G. In twelve of the fifteen dogs maintained on the deficient ration a slowly progressive disease developed, characterized by loss of weight, vomiting and bloody diarrhea, flaccid muscular weakness, incoordination and decrease of the deep reflexes. Death occurred in from 107 to 599 days. The acute symptoms could be modified and the life of the animal prolonged by the administration of a minimal amount of vitamin G, 0.05 Gm. of liver extract per kilogram of body weight daily. This permitted the gradual development of the neurologic signs to a more marked degree. In each of the twelve control animals receiving an adequate amount of vitamin G, neither the clinical nor the pathologic manifestations of the disease developed. The lesions consist of marked demyelination of the peripheral nerves and degeneration of their axis cylinders. Many medullary sheaths and axis cylinders of the posterior columns are also destroyed and replaced by gliosis. The degenerative changes in the nervous system are similar to those observed in cases of human pellagra.

Myxedema.—Kitchen believes that, in spite of the well established clinical nature of myxedema, many cases are overlooked for years. Some of the patients one sees do not follow the clinical pattern in detail, and a diagnosis is made with reluctance. The pulse rate may be normal or the blood pressure elevated and the weight not excessive, so the possibility is dismissed. Or occasionally, when doubt exists, a basal metabolic reading may be taken and found to be only minus 18 or 20 and this seems hardly low enough, since minus 35 at least is expected. A low basal metabolic rate is valuable confirmatory evidence, but it should never confuse one's clinical judgment. Then, too, there may be no history of intolerance to cold or undue fatigability, because these people have for years been accustomed to a low threshold of activity and to wearing sweaters in an indoor atmosphere of 80 F. and much extra clothing when venturing outdoors. There is no reason why they should voluntarily mention these facts, as to them these are not ailments but constitute a perfectly normal condition. The greatest source of error in diagnosis, however, arises from the fact that these patients often present themselves for examination because of one particular symptom (menorrhagia, neuritic or joint pains, flatulent dyspepsia, albuminuria, anemia or obstinate constipation) which is so annoying that it banishes thought of any minor discomforts which they may experience. As a result, one is prone to focus attention on the symptom, forgetting the individual, and so it happens that not infrequently he may be treated for anemia, dyspepsia, arthritis, nephritis, constipation or some other complaint, and many months may elapse before the real diagnosis is made.

Epilepsy in General Practice.—Armour warns that young epileptic patients should not be left to "grow out of" the condition. Repeated convulsive attacks in infancy and early childhood probably tend to create or increase an "epileptic

potentiality." Perhaps one of the greatest mistakes is to regard epilepsy as exclusively a nervous disease to be treated only by the specialist. Many practitioners are puzzled because they fail to find abnormal physical signs in their examination of the nervous system. More and more are constitutional and metabolic diseases complicated by the epileptic state. Early gastro-intestinal disturbances, neglected and leading to repeated convulsions, would seem to have a great influence in establishing the epileptic potentiality. The headache, dizziness and occasional delirium following sunstroke due to excessive sunbathing must surely indicate vascular disturbances, such as great congestion and edema or even minute hemorrhages. "Epilepsy" is not a disease in itself. It is probably the occasional expression of many different diseases or abnormalities.

Protamine Insulin.—Marble believes that protamine insulin in its present or in an even more perfected form has come to stay, or at least that some slowly acting preparation closely akin to it will in the future form a valuable part of the physician's armamentarium. With it there is a means of controlling diabetes for twenty-four hours of the day. Protamine insulin can be used with benefit in practically every case. In the author's experience the best results have been obtained with protamine insulin to which a trace of zinc has been added. The insulin and the protamine solution, kept separately, are stable indefinitely. Many patients, including all mild and some of the moderately severe cases, can be controlled on one daily dose of protamine insulin alone. There is little or no evidence to indicate that the small amounts of zinc present in protamine zinc insulin may give rise to toxic effects.

Psychosis Following Administration of Atabrine for Malaria.—The Allens and Fulghum observed nine patients who presented evidence of toxic psychosis in which atabrine was the principal causative factor. Five of these patients showed wild excitement closely resembling the manic type, two showed mild excitement with confusion, and two showed almost no excitement but severe confusion. Only four of the nine patients had had previous nervous or mental symptoms: one had been mildly excited over religion, one had an undescribed nervous episode when young, another had a psychopathic personality and one had an undiscovered paresis. Six patients had associated physical conditions that could have been predisposing factors. Five of the nine patients had had quinine in addition to atabrine. Only one patient failed to develop yellow pigmentation. Distress of the upper part of the abdomen occurred in one third of the series and was always the high, transverse,

colon type of distress. Further proof of this relationship must await appropriate chemical studies of the excretion of the drug, such as the glacial acetic acid test of the urine for delayed excretion. Other factors that may delay excretion should be watched for while the patient is under active treatment, such as constipation, kidney insufficiency, insufficient liquid intake or loss of blood liquids that may result from insufficient nourishment, high fever, excessive exercise and sweating. Yellow pigmentation is a warning complication. Evidently the pigmentation can be seen only in the skin of the lightest colored races. The dosage of atabrine should perhaps be more closely correlated to body weight. The three patients who took less than 25 mg. of atabrine per kilogram of body weight had symptoms for less than three days. Each patient with manic depressive symptoms, even though transient, should be followed up over a period of years to learn whether attacks recur independent of atabrine.

Gonadotropic Hormones in Treatment of Experimental Tuberculosis.—Of all the animals treated with antuitrin-S (six rabbits and seventeen guinea-pigs) by Steinbach and Klein, only two guinea-pigs failed to show less tuberculosis than did the corresponding controls. Gonadotropic substance, which contains the same principle, also proved of value in retarding the progress of disease. It appears possible that the poorer results obtained with gonadotropic substance may be due to the high concentration of glycerol present in this preparation. Long and Vorwald have shown that injection of glycerol enhances the multiplication of tubercle bacilli in rats. Pregnant mare serum, which is a rich source of gonadotropic substance, proved efficacious in retarding tuberculosis. Anterior pituitary extract proved of no value in retarding the progress of the disease, and in many instances animals treated with this substance showed more tuberculosis than did the controls. Pla-

cental extract (emmenin) given by mouth was likewise entirely ineffective in preventing progress of the disease. The results obtained suggest that the gonadotropic principle which appears during pregnancy may be an important factor in the increased resistance displayed by the pregnant tuberculous woman. The breakdown of this resistance that occurs during the later stages of pregnancy may perhaps be correlated with the diminution of this hormone, which begins after about the fifth or sixth month and ends with the entire disappearance of the hormone a few days after delivery.

Rapid Invasion of Body Through Olfactory Mucosa.—Rake observed that prussian blue particles pass rapidly from the surface of the olfactory mucosa and within two minutes are found in the tissue spaces, in blood and lymph vessels, in the perineural spaces of the olfactory nerve fibers and in the subarachnoid space and pia-arachnoid membrane. Preliminary treatment of the olfactory mucosa with tannic acid does not alter the speed with which this absorption occurs. It does, however, cause an inflammation of the mucosa and appears to prevent the pigment from entering the olfactory sensory cells. Both pneumococci and Salmonella enteritidis pass through the olfactory mucosa and reach the tissue spaces, the vessels and the subarachnoid space with the same rapidity as the pigment. They invade by passage between the cells of the mucosa and there is no apparent affinity of the organisms for the olfactory sensory cells. Tannic acid treatment of the olfactory mucosa in no way alters this invasion of organisms through the mucosa. The pantropic virus, equine encephalomyelitis, was detected in the forebrain as promptly as were pigment and bacteria; neurotropic viruses, however—those of St. Louis encephalitis, rabies and louping ill—were not demonstrated in less than twenty-four hours.

Study of Recurrence Following Operations for Nephrolithiasis.—Twinem reviewed 314 cases of operation for nephrolithiasis. The percentage of recurrence following pyelotomy was 20.9 and the percentage of recurrence following nephrotomy, 28. The greater incidence following nephrotomy agrees with the results of other investigators, but this point should

be interpreted with some qualification since the type of operation originally selected depends on the size, shape, number and location of the stones. The percentage of recurrence following operations for multiple stones was greater than that following operations for single stones. The frequency of pseudorecurrence is considerable and, to avoid this possibility, roentgenograms should be taken on the operating table particularly in cases of multiple and staghorn calculi. Heminephrectomy should probably be employed more frequently than it has been by most operators. The low percentage of recurrence in the opposite kidney following both nephrectomy and conservative operation indicates the importance of local factors in stone formation. Phosphatic calculi were found to recur more frequently than calculi of other composition, except those composed of cystine. The ten cases most frequently recurring were all either primarily or secondarily infected. The importance of *Bacillus proteus* in these persistently recurring cases is emphasized. The possibility of the presence of hyperparathyroidism should be investigated, particularly in the bilateral and recurring cases.

Electrolyte, Water and Acid Base Balance Studies in Renal Disease.—Piersol discusses only vascular renal disease. Whether the primary lesion involves the capillaries of the glomerular tufts or the endothelium of the afferent arterioles to the glomeruli, the ultimate effect is to disturb normal renal function. When the principal changes are in the arterioles, the vascular disturbance is by no means confined to the kidneys but is a systemic involvement. There is no symptom complex associated with renal insufficiency that is of more clinical importance than the phenomena called uremia. The clinical manifestations of true uremia are correlated in some way with retention in the blood of waste products that should have been eliminated by the kidneys. The most serious and lethal manifestation of true uremia is uremic coma always with definite acidosis. There is no relationship between uremic coma and the height of the blood urea. In acidosis of renal origin there

is a decrease in the plasma carbon dioxide combining power and an increase in the inorganic phosphates and sulfates of the blood. There may be associated reduction of total base and "starvation ketosis." When systemic blood pressure in a patient with chronic nephritis falls to a level below the effective glomerular filtration pressure, renal function will be impaired markedly and uremic coma may result. Cases of hypochloremia with high blood urea are often mistaken for true uremia. The hyperazotemia and increased plasma carbon dioxide are part of a compensatory mechanism for the maintenance of osmotic pressure of body fluids. Unless hypertension preexists, these cases will show no elevation of blood pressure; on the contrary, there is often a lowered blood pressure. Chronically diseased kidneys eliminate sodium chloride only in low concentration. Even when no edema is present, it is important to regulate the sodium chloride intake so as to preserve a normal electrolyte level in order to maintain a normal osmotic pressure. Water intake in a nephritic patient must be regulated in accordance with the electrolyte level, the quantity of total plasma proteins present and the efficiency of the myocardium. The maximal amount possible under the existing conditions should be given. The patient with chronic vascular nephritis in whom the condition is no longer progressive may live in reasonable comfort if properly standardized and maintained in water, sodium chloride, alkali and protein balances. In the more acute progressive cases this cannot be done successfully.

*Osteomyelitis of Skull. E. F. Fincher Jr., Atlanta, Ga.—p. 53.

Lesions of Lower Portion of Esophagus.—Vinson states that too frequently it is assumed that indefinite digestive discomfort characterized by distress after meals, gas, fullness in the epigastrium and epigastric pain are the result of disease in the gallbladder. Examination of almost every gallbladder removed at operation will reveal evidence of infection, and the physician and the patient will be disappointed when removal of that organ fails to relieve distress that was thought to be the result of cholecystitis. A more careful preoperative consideration of the esophagus and cardiac portion of the stomach in patients suffering from obscure digestive discomfort will eliminate many errors in diagnosis and decrease the frequency of the useless operations on the stomach and gallbladder. Dysphagia is the most frequent symptom of esophageal disease. Carcinoma of the esophagus and cardiac portion of the stomach is usually associated with dysphagia. Epigastric pain is fre-

quently an early symptom in cardiospasm and may be present for many months or years before other symptoms appear. Inflammation involving the lower portion of the esophagus may be associated with burning beneath the sternum and hematemesis. In the acute stage such inflammation can rarely be differentiated from acute gastritis and, if it becomes chronic, the symptoms may simulate those of peptic ulcer. Healing of the ulceration may result in the formation of a stricture with associated dysphagia. Benign tumors of the esophagus are rarely observed and do not produce symptoms of obstruction until they have attained considerable size. Hernia of a portion of the stomach through the esophageal hiatus in the diaphragm is so closely associated with the esophagus that it can be considered an esophageal lesion.

Osteomyelitis of Skull.—Fincher gives a number of detailed facts concerning the development, course, treatment and results of osteomyelitis of the skull. Individual case reports of variable etiologic background, illustrating the problems and management of these cases, are presented. There are a few instances in which the extensiveness of the disease and the associated debilitating effects on the patient prohibited radical surgical efforts. The complications and sequels of the disease are all so dangerous that early recognition is the answer for prevention, and radical surgical removal of all infected skull is the choice of treatment.

Syphilis and Pregnancy.—Point declares that seventy-five out of 100 syphilitic children die within the first year of life (Adams), generally within the first week, and are always an easy prey to infections and intestinal disturbances. The remaining 25 per cent have latent syphilis, which manifests itself usually before the nineteenth year. The generally accepted theory today is that the disease is always transmitted from the mother to the child in utero by way of the placental circulation. Therefore syphilis is congenital and not hereditary. Spirochetal manifestations in the fetus depend on the duration of the mother's syphilis and the stage of the development of the fetus. If infection of the mother takes place a short time before conception, the fetus is almost certain to die in utero. The longer the mother has syphilis before conception, the more probable is the birth of a macerated fetus, a premature child, a stillborn child or a living child with latent syphilis. Syphilitic abortions do not occur before the fourth month; at least, spirochetes have never been found in such early stages of the placenta. Every syphilitic gravida must be treated, regardless of the amount of treatment received before conception and irrespective of the absence of symptoms. The same treatment is required in each succeeding pregnancy. The earlier in pregnancy treatment is instituted, the greater are the chances for the birth of a living and healthy child. No matter how late in pregnancy maternal syphilis is recognized, intensive, systematic treatment must be given. The arsenicals have definitely proved their superiority over mercury for this prophylactic purpose. Abortion or fetal death need not be feared from intravenous injection.

Treatment of Tobacco Amblyopia by Acetylcholine.—Since July 1936 Cragg has treated five male patients suffering from tobacco amblyopia by the intramuscular injection of acetylcholine bromide. This drug is available in two doses, dose A being 0.03 Gm. and dose B 0.125 Gm. Each patient first received two injections of dose A with one clear day's interval between, and then a daily injection of dose B until no further treatment was considered necessary or until improvement ceased. In addition, patients 4 and 5 were given $\frac{1}{150}$ grain (0.004 Gm.) of physostigmine sulfate daily by mouth, following the suggestion that the action of acetylcholine is enhanced by minute doses of this drug. The results were encouraging: treatment by this method gives more rapid improvement in vision. The patient in most cases realizes that overindulgence in tobacco has been the cause of his defective vision.

Autogenous Urinary Proteose in Asthma.—In assessing the therapeutic effects of proteose, Libman and Bigland realized that even if proteose was not specific in its action, as claimed by Oriel, some therapeutic benefit might be obtained, as often happens with nonspecific injections. Proteose was administered to a series of fifty-eight patients, composed of forty-eight cases of asthma and ten cases of various allergic skin conditions. Autogenous proteose was prepared from the urine in every case. The investigations tend to confirm the view that the zone of erythema obtained at the site of intradermal injection of urinary proteose is probably nothing more than a local toxic reaction and is not in any way specific. The therapeutic benefit obtained with injections of autogenous urinary proteose in cases of asthma is about the same as that obtained with peptone. Any specificity that may be claimed for the former method does not outweigh the many advantages of a simpler and more general form of desensitization such as can be obtained with peptone. Treatment with peptone can be begun at any time, no laboratory preparation is necessary, the same degree of therapeutic value is obtained, and the treatment is relatively cheap.

The Nose and Throat and Rheumatic Fever.—According to Barwell, an attack of acute rheumatism or rheumatic fever is normally preceded by an acute infection of the fauces with a hemolytic streptococcus, which often is only of slight severity. It is usually a clinically mild and transient infection of the throat that precedes the most severe attacks of rheumatic fever. After this there is a symptom-free interval of from a few days to a few weeks before the onset of rheumatic symptoms. Further attacks, or recurrences, of acute rheumatism are similarly preceded by streptococcal pharyngitis. There is little room for doubt, then, that acute rheumatism is caused by streptococcal infection, but the mechanism by which the effect is produced is still uncertain. It does not appear to be a septicemia, and suppuration never occurs; it seems rather to be related to a faulty method of dealing with bacterial toxins. There seems to be a definite delay in the immune responses of rheumatic, compared with those of nonrheumatic, people, and the patient who develops an attack of rheumatic fever "handles the products of the hemolytic streptococcus in a peculiar way" (Coburn). It would seem to be this peculiar response which determines the incidence of acute rheumatism. The incidence of acute infection of the fauces is diminished by tonsillectomy. When, therefore, a sore throat has been followed by rheumatic fever, it is proper that the tonsils should be removed. But numerous smaller nodules of lymphoid tissue remain scattered over the pharynx, and acute pharyngitis can and does occur after tonsillectomy, so that this operation does not with certainty prevent recurrence of acute rheumatism, though it makes it less probable.

*Studies on Transmission of Relapsing Fever in North China: I. Preliminary Observations. H.-L. Chung.—p. 1723.

Transmission of Relapsing Fever in North China.—Chung declares that the majority of patients with relapsing fever seen at the Peiping Union Medical College Hospital harbor human body lice. This fact together with the geographic, climatic and other epidemiologic factors lends support

to the view that relapsing fever in North China is essentially a louse-borne disease. The fact that he has been successful in recovering spirochetes from body lice captured from patients constitutes evidence in favor of this view. That bedbugs may play a part in the spread of relapsing fever has not received due attention. It is likely that, when a systematic examination is made of bedbugs recovered from the belongings of relapsing fever patients, infected bugs will be found more often than would be anticipated. The author has shown that bedbugs can be infected with *Spirochaeta recurrentis* by feeding on Chinese squirrels experimentally infected with relapsing fever. *Spirochaeta recurrentis* can survive at least twenty-five and one-half hours in bedbugs and remain virulent for the squirrel. Bedbugs may serve as vectors in the spread of the disease. Infection can take place easily through contact of the organisms with the normal skin or mucous membranes.

Racial Variations in Sweat Secretion on Axilla. K. Kashiwabara and K. Ogata.—p. 122.

Method for Suppression of Local Sweating.—Ichihashi used repeated applications of formaldehyde by cataphoresis for the treatment of hyperhidrosis. This was done with great success in thirteen patients suffering from excessive hyperhidrosis of the palms and soles, seven suffering from hyperhidrosis of the axilla and fifteen who suffered from osmidrosis. It was especially successful in the case of palmar hyperhidrosis. A treatment consisting of three or four cataphoretic applications stopped the suffering entirely for at least one and one-half months, sometimes longer than two months. But strong hornification of the skin, followed by desquamation, occurred in the treated region of the skin. In the axilla, a strong application, such as to cause desquamation, could not be used. But the hyperhidrotic suffering could be cured for about one month or longer by a series of applications. In osmidrosis, this treatment was less successful so that a good effect could be expected for only two or three weeks. This was probably because suppression of the generation of the odor was possible only as long as the secretion was entirely stopped. On the palms and soles, a 7.5 to 10 per cent solution of formaldehyde will be cataphorized with a current of one-third to one-half milliampere per square centimeter of skin for ten minutes. For the axilla, the solution should be from 5 to 7.5 per cent, and the current from one-fourth to one-third milliampere per square centimeter of skin for five minutes. The anode should be applied to the regions to be treated and the cathode to some indifferent part of the skin. These procedures should be repeated three or four times at intervals of about two days.

Treatment of Lambliasis.—Irazabal-Luigui, reviewing the treatments of *Giardia intestinalis*, notices that almost all mineral and organic substances having an antiseptic or antiparasitic action have been tried and have failed. The disease resists every therapeutic measure because no specific remedy has as yet been discovered. In his effort to make that discovery he infected a number of white mice and began treating them with medicaments recently used and advocated by others. First of these was *Jacaranda decurrens*, known as tincture of carobine, allegedly used by Peckolt and Prado with excellent results. But the medicament did not seem to affect his mice in the least and it was not even toxic. The author then made experiments with pyrethrine, gentian violet and acetarsone with negative results. Resorting to naphthalene, previously used by Sorge, he administered the purified substance in increasing doses. Only one good result was obtained in a mouse with a feeble infection. Finally he continued his experiments with essence of turpentine, with which Deglos, Escomel and others had obtained good effects and which he administered in a mucilaginous solution. Of ten mice, six were decidedly freed of parasites so that at necropsy no live forms were found. Two others of the ten were notably improved and in two the drug proved itself ineffective. From the results obtained the author draws the conclusion that essence of turpentine, although no specific remedy, is capable of rendering good services in the treatment of lambliasis.

Spasmodic Intestinal Complications in Pernicious Anemia.—In the course of Biermer's anemia there are signs of gastric pseudotumors which clinically have the symptoms of pyloric constriction and roentgenologically look as though the pylorus were amputated. These disorders seem to be due to muscular spasms of dyspeptic patients and disappear with Biermer's liver treatment. Émile-Weil and Menetrier present two cases of pernicious anemia. In one there were symptoms of intestinal constriction with physical and functional disorders, and in the other signs of incomplete intestinal occlusion with painful crises lasting for about two weeks. In the first case an exploratory operation was done and no intestinal or gastric lesions were found. The patient has now been well for three years under liver treatment. In the second patient, who had a painful intestinal tumor in the right hypochondrium and who often had symptoms of occlusion, belladonna and liver extract brought about complete cessation of symptoms, which have not returned since the blood picture was improved.

 Purgative Action of Castor Oil. R. Hazard.—p. 142.

Antivariola Viruses.—Gallardo and Sanz cultured variola viruses in vitro and on the allantoïd of the chicken embryo and reproduced the characteristics of their original species. An

embryo of about ten or twelve days is deprived of its eyes and well washed with Tyrode's solution. It is placed in a large watch glass and finely chopped by means of the curved scissors used by ophthalmologists. Then from 7 to 8 cc. of Tyrode's solution is added. To each 4.25 cc. of Tyrode's solution previously distributed into small bottles they add 0.25 cc. of this embryonic suspension. For cultures in 50 cc. bottles they begin with 0.5 cc. of the virus of known purity and activity. The following is the formula: Tyrode's solution 4.25 cc., embryonic suspension 0.25 cc., initial or passage virus 0.5 cc. For larger bottles this formula is proportionately increased. Under such conditions a filtrate will furnish a pure lymph, rich in virus. Subcutaneous vaccination with cultures in vitro or on allantoïd gives a positive reaction similar to that obtained with the best lymphs used on the skin. This virus gives local and general reactions which are less intense than in skin vaccinations; no reaction indicates probable immunity. Pustules are not formed.

Withdrawal of Blood for Culture in Epinephrine-Induced Spleen Contraction.—Irdelp and his collaborators withdraw blood before and after the injection of 1 mg. of epinephrine hydrochloride. This was done in forty-nine cases of typhoid with the object of inducing a spleen contraction in an effort to drive the micro-organisms into the blood stream. In 59.5 per cent of the cases it was shown that the preceding injection of epinephrine noticeably increases the possibilities of positive results in blood culture. It is advisable to use the method in other infectious diseases as well.

- *Treatment of Burns by Applications of Vitamin A. Chevallier, F. Carcassonne and Luccioni.—p. 89.
 Obesity in the Child. S. B. Briskas.—p. 90.

Vitamin A in Treatment of Burns.—A patient with burns is not only wounded but in danger from resorption of toxins, and cellular recovery is slowed through local and general circumstances. Having occasion to study the effect of vitamin A on the scar formation of wounds, Chevallier and his associates applied it to five severe burns with the result that recuperation was rapid, pain disappeared, the temperature came back to normal and the scars remained soft and pliable. They spread a solution of vitamin A in cod liver oil on sterile gauze. Later dressings consisted of applications of a solution of 0.25:1,000 of methylene blue alternating with vitamin A. The general condition was restored and a good tendency to healing appeared after five days in three cases. In the two other grave cases admitted a few days after the accident the same results were obtained in twenty-five and twenty-eight days, respectively. It seems that vitamin A is absorbed in large quantities, turning the local into a general treatment. The authors do not mention the percentage of vitamin A used.

 *Relaxation of Diaphragm. G. Töndury.—p. 142.
 Treatment of Traumatic Central Dislocation of Hip Joint. M. Richard.—p. 144.

Ichthammol in Wound Treatment.—Bosch says that, applied to the skin, ichthammol exerts a vasoconstrictive effect and produces epithelization. After he had heard from Bleuler that ichthammol can be used in the form of a 5 per cent aqueous solution for moist applications, he decided to use this solution whenever an antiphlogistic action was required; that is, in infected wounds. In doing this he observed that the inflammation was reduced and that there was also a noticeable

decrease in the wound secretion. The latter characteristic was especially noticeable in case of infected surface wounds. The author repeatedly noticed cases in which considerable pus secretion disappeared twenty-four hours after the application of the ichthammol compress and he concluded that the aqueous solution of ichthammol in the partially moist chamber (gutta percha cover over the compress) exerts a destructive effect on the bacterial flora. In order to verify this effect, he tested the bactericidal effect of the solution in vitro and found it especially powerful against hemolytic streptococci, but also against enterococci and pyococci. The colon bacillus, however, was an exception. The author tried the solution in fresh accidental wounds, in those that had been sutured as well as in those that had not been sutured, and found it quite satisfactory. As a special advantage he stresses that the change of bandage is painless, even if the compress has dried.

Relaxation of Diaphragm.—Töndury defines relaxation of the diaphragm as a unilateral elevation, which is usually on the left side and which frequently causes disorders. He says that reports about this condition discuss the clinical and roentgenologic aspects and the differential diagnosis but that few give information about the anatomic aspects. He therefore describes the anatomic and microscopic aspects of two cases that came to necropsy. In the first case the elevated left half of the diaphragm was thin; its muscle fibers were atrophic and separated and the phrenic nerve was degenerated. The author thinks that the degeneration of the phrenic nerve resulted in the muscular atrophy. In the second case, however, the muscular atrophy was primary and the atrophy of the phrenic nerve was secondary. In the latter case a dextroconvex dorsal scoliosis and a levoconvex lumbar scoliosis of the vertebral column was a genetic factor in the relaxation of the diaphragm.

Relation Between Intermediary Metabolism of Carbohydrates and Energy Metabolism.—Stefanutti studied the variations of the respiratory quotient and of glycemia in normal persons, in diabetic patients and in patients suffering from heart diseases (compensated and decompensated) after administration of dextrose by mouth, with and without simultaneous administration of a subcutaneous injection of insulin. Oral administration of dextrose induces a moderate increase of the specific dynamic action and of the respiratory quotient in normal persons and slight and irregular metabolic variations (or none at all) in diabetic patients and in persons suffering from heart diseases. In normal persons the respiratory quotient increased less by simultaneous administration of dextrose and insulin than by dextrose alone, and the specific dynamic action was abolished. In diabetic patients and in persons suffering from heart diseases the respiratory quotient and the specific dynamic action greatly increased by the associated administration of dextrose and insulin. According to the author, the specific dynamic action which follows administration of dextrose by mouth is less intense than that induced by proteins. It is due to an increase of intra-organic combustions during the process of direct oxidation of dextrose and is slight (or does not take place at all) in persons suffering from functional disturbances of gastric absorption or of the intermediary metabolism of the carbohydrates. The latter is disturbed in diabetic patients as well as in those suffering from heart diseases. The different behavior of insulin on the specific dynamic action of normal persons, diabetic patients and those suffering from heart diseases is due to the fact that in normal persons the insulin stimulates the formation of liver glycogen, whereas in the others it improves the metabolism of carbohydrates with consequent complete oxidation of the sugars.

Tuberculosis and Rheumatic Fever.—Pellegrini reports three cases of pulmonary tuberculosis in association with rheumatic fever. In the differential diagnosis the history of the patient is of value in showing previous or actual contact with tuberculous patients or occurrence of local inflammation and infection, especially in the throat, pharynx, upper respiratory tract and teeth. The different types of fever and sweats, the results of the physical examination of the thorax and of the tuberculin and the speed of sedimentation tests and the presence of certain alterations in the blood, which are different in pulmonary tuberculosis and in rheumatic fever, are also of value. The favorable results of the administration of salicylate is the most important fact in the differential diagnosis. According to the author, there is no antagonism between rheumatic fever and pulmonary tuberculosis. The coexistence of the two diseases is frequent. The symptoms of one or the other disease may prevail, they may run parallel or they may alternate. It is possible that the viruses of the two diseases have reciprocal etiopathogenic relations owing to certain phenomena of the nature of Sanarelli-Schwartzman's phenomenon.

Relation Between Obstruction of Nose and Development of Paranasal Sinuses. S. Barbera.—p. 563.

Treatment of Tuberculous Laryngitis.—Rubaltelli reviews the literature and states that the results obtained with either periarterial sympathectomy or roentgen treatment in tuberculous laryngitis are identical. Both treatments control mechanical painful dysphagia and produce reflex intralaryngeal vasodilatation. The results reported in the literature concerning the effects of either treatment on infiltration or ulceration of the laryngeal mucosa are conflicting. The roentgen treatment is preferable to sympathectomy. It can be administered in all cases, regardless of the local condition of the disease and of the general condition of the patient. If the roentgen treatment is given in the precise dose and with the proper technic, accidents and complications do not follow. It is advisable to avoid, whenever possible, bleeding, prolonged or complicated operations in tuberculous patients. The roentgen treatment can be given as an ambulatory treatment and be repeated at certain intervals. The benefits of repeated roentgen therapy are more lasting than those obtained from sympathectomy.

*Grave Syndrome of Myelradicular Neuritis in Course of Atabrine Therapy: Case. P. Valentini.—p. 51.
Duodenal Ulcer in Child: Case. F. Menna.—p. 60.

Total Acidity and Lactic Acid in Blood Serum of Infants.—Cammarella determined the relation between the total amount of organic acids and lactic acid in the blood serum of infants in normal and pathologic conditions, using the Csapó and Mendel-Goldscheider methods. The figures obtained for organic acids varied between 9.1 and 13.8 of a tenth normal

solution of acids per hundred cubic centimeters of blood serum of normal infants. The amount of lactic acid of normal infants varied between 20.5 and 50 mg. per hundred cubic centimeters, depending on the psychomotor activity of the infant at the time of blood withdrawal. In general, the figures for the total organic acids, lactic acid and other organic acids are the same in normal infants, children and adults. In pathologic cases the behavior of lactic acid does not parallel that of total organic acids. In cases of laryngospasm the figures for lactic acid are high, whereas those for the total organic acids are normal (diminution of the remaining organic acids in the blood). In cases of bronchopneumonia and of toxicosis the figures for lactic acid are high or normal and those for the total organic acids are high. The lack of parallelism between the amount of total organic acids and lactic acid in the blood serum of infants in pathologic conditions shows that the metabolism of carbohydrates is not necessarily involved in the disturbances of the intermediary metabolism. The involvement of the metabolism of the carbohydrates in the pathologic process depends on the intensity of the hepatic dysfunction induced by the pathologic process. The increased total organic acidity is due to increased production of organic acids and decreased renal elimination with consequent retention and accumulation of the acids in the blood.

Myeloradicular Neuritis in Course of Treatment with Atabrine.—Valentini points out the toxicity of atabrine (an amino acridine derivative) in the treatment of malaria in children and advises that small doses be used. A case of acute cerebrospinal polyneuritis in a child who was given this drug is reported in the literature (Moschini). The author reports a case of grave myeloradicular neuritis in a child, aged 5 years, who suffered from malaria and was given a daily dose of 0.03 Gm. for five consecutive days. The patient developed a syndrome of grave flaccid paralysis of the muscles of the trunk and of the extremities and disturbances of respiration and of the liver and vomiting. The immediate treatment consisted of hypodermoclysis, stimulants and tonics, as well as belladonna for controlling the vomiting. Later strychnine, epinephrine, iron and arsenic were given, diathermy was applied, and physical and respiratory exercises were performed by the patient. The grave symptoms ameliorated but those produced by disturbances of the nervous system have remained stationary for eighty days.

8: 641-704 (Nov.) 1936

Colloidal Lability and Obstruction Phenomenon in Urine. C. Franzolin.—p. 641.

*Revival of Male Breast. A. Visani.—p. 650.

Lipases in Blood Serum in Normal and Pathologic Conditions. L. Franzi.—p. 665.

Poisoning from Snake Poisons. L. Franzi.—p. 693.

Revival of Male Breast.—Visani reports four cases of revival of the breast in men who were suffering from different diseases. None of the patients showed alterations of the genitalia. According to the author, gynecomasty may originate in endocrine, constitutional, nervous, infectious, humoral or circulatory disturbances. The most important pathogenic factor is the presence of circulatory stases in the region of the breast. When the organic disturbance that produces gynecomasty in the given case is favorably modified, the hypertrophy of the breast regresses. The treatment should aim at controlling the organic disturbances which cause gynecomasty. Amputation of the breast is an unnecessary mutilation because gynecomasty is merely a symptom of an organic disturbance.

*Control of Bleeding with Autogenous Tissue. Heilingbrunner and Schörcher.—p. 475.

Control of Bleeding.—According to Heilingbrunner and Schörcher, cessation of bleeding is a complicated physiologic process. Cessation of bleeding and blood coagulation are two

independent processes. Bleeding from a severed vessel comes to an end not because of the formation of a thrombus but because of a contraction of the vessel. Several factors play a part in the stoppage of bleeding. A blood clot cannot form as long as blood continues to flow; therefore slowing of the blood current in the severed vessel is the most important condition for coagulation. The contraction of the severed vessel serves this purpose. Contraction of the severed vessel leads to the agglutination of its walls, in which event formation of a thrombus is no longer necessary for the arrest of bleeding. Magnus demonstrated in man that a severed capillary in the bed of a nail contracts in its entire length and remains permanently contracted. In the case of larger vessels the initial contraction is followed by relaxation and it is at this moment that thrombus formation takes place and plays its part. Thus the formation of a blood clot is the final act in the cessation of bleeding. The authors demonstrated in their experiment that the addition of watery extract of macerated autogenous muscle or fat tissues to the human blood reduced its coagulation time by one half. They believe that this effect is due to the mechanical effect of interfering with the blood flow and to the thrombokinase released from the tissue by maceration. Peritoneal tissue, when applied to a bleeding surface, had no effect, but, when it was macerated, the effect was at once evident. Macerated thyroid tissue was not more effective than muscle or fat. The authors applied muscle or fat tissue to the abraded surface of the liver of a rabbit and observed that the bleeding was arrested in from two to three minutes, whereas the surface not so treated continued to bleed. Bleeding from an abraded skin surface of the hind leg of a rabbit was stopped in from one to one and one-half minutes by application of macerated muscle or fat tissue, whereas the portion not so treated continued to bleed for from four to five minutes. The authors likewise found this method effective in arresting bleeding in surgical procedures on the brain in dogs.

Myeloid Reaction in Diseases of the Blood.—Schmengler and Krause report three cases of panmyelophthisis and one case of aleukemic myelosis, in all of which there was toward the end a considerable flooding out of myeloid cell forms. The authors interpret these cases as the result of the blockage of the bone marrow, the cause of which is unknown, although hypersplenism might have played a part in the case of aleukemic myelosis. Later, as the result of the interruption of the blockage, a myeloid reaction followed. In two cases the interruption of the blockage was probably effected under the stimulus of the constant loss of blood, in another case under the influence of a superimposed secondary general infection and in the fourth case perhaps by the exclusion of the influence of the spleen after splenectomy. The first three cases showed only a myeloid reaction, not a leukemia. In the fourth case the aleukemic phase was followed, as in the first three, by a leukemoid one. To be sure there was the difference that in this case there was a true leukemia from the beginning and a leukenemia was simulated in the aleukemic stage of this leukemia. The possibility of the transition of true agranulocytosis and of true panmyelophthisis into acute leukemia is rejected by the authors.

Diabetes Mellitus, Gallbladder and Obesity.—Terbrüggen decided to make a statistical analysis of a necropsy material with regard to the connection existing between age, obesity and cholecystopathy and between age, obesity and diabetes mellitus. In diabetic patients of less than 50 years of age, he never noticed a combination with cholecystopathy. In diabetic patients between the ages of 30 and 50, obesity was compara-

tively frequent and in those beyond the age of 50 it was extremely frequent. The author thinks that the concurrence of diabetes with gallstones is not so frequent as to suggest a causal connection with diabetes mellitus; thus there is no reason to regard diabetes mellitus as a sequel to biliary disease. The author explains the concurrence of biliary disorders and diabetes mellitus as the result of obesity, which occurs in both conditions. He suggests that on the one hand obesity favors the development of biliary disorders, and, on the other hand, in case of a predisposition, it also leads to the manifestation of diabetes mellitus.

Gastric Acidity and Calcium Metabolism.—Thiele demonstrates that the calcium content of the blood and the acidity of the stomach run parallel; that is, the calcium content is the higher, the greater is the acidity of the stomach. The calcium values of the blood are especially low in gastric carcinoma. The intravenous administration of calcium effects an increase in the gastric acidity.

Electrocardiographic Changes and Prognosis of Myocardial Diseases.—May points out that, although it is comparatively simple to determine the existence of a myocardial defect from the electrocardiogram, it is difficult to estimate the condition of the cardiac muscle from a single electrocardiographic record. One electrocardiographic examination indicates only the presence of changes but not how long they have existed. In this connection the author directs attention to the electrocardiographic records of branch block in older persons who feel slight or no discomfort. However, a careful anamnesis frequently reveals that cardiac symptoms existed a long time before. It is probable that changes developed at that time but that subsequently the basic disorder was arrested and the electrocardiographic change was the only sign that remained. New myocardial lesions become manifest in rapidly changing electrocardiograms. In this connection the author mentions the rapidly (daily or even hourly) changing electrocardiographic records in myocardial lesions that are caused by changes in the coronary vessels or by diphtheritic lesions in the cardiac muscle. The most important characteristic of the new myocardial lesion is the cessation of the uniformity of the electrocardiogram. The author describes a series of electrocardiograms that were made in the course of several weeks of a woman, aged 48, who complained of fatigue, numbness in the hands and feet, occasional swelling of the feet and attacks of cardiac oppression. The electrocardiographic records made at intervals of several days revealed various changes in the cardiac conduction system. The author shows the difficulties that are encountered in the interpretation of the successive electrocardiograms, but he says that, in spite of the fact that at first there was a lack of symptoms, the constantly changing electrocardiographic records indicated an unfavorable prognosis. This was later corroborated by the development of a circulatory insufficiency.

Value of Klein's Reaction for Diagnosis of Cancer.—Lönne points out that the method for the diagnosis of cancer which Klein developed on the basis of the studies of Freund and Kaminer has been widely discussed recently but that only

a few have doubted the value of this reaction. For this reason he feels justified in reporting the results that were obtained in his own material of ninety-eight cases. Only sixty-nine fulfilled the requirements for the test and twenty-five of this number had clinically demonstrated cancer while forty-four were free from it. Two specimens from many of these patients were submitted for testing, with the result that the reaction showed positive as well as negative results in some cases. Only one specimen each of nine patients with cancer was tested and three gave a positive reaction while six gave a negative, that is, an incorrect, result. In the forty-four patients without cancer the reactions showed a higher percentage of correctness, but, of the group of thirty-five in whom double tests were made, seven gave positive as well as negative reactions. A survey of the entire material reveals 72.5 per cent correct and 27.5 per cent incorrect reactions. The author thinks that the test can be considered of definite value only if a correctness of at least 90 per cent can be reached and therefore he rejects the general use of the reaction in its present form.

Peritonitis a Circulatory Problem.—Friedrich shows that the peripheral circulation should receive attention in the treatment of peritonitis. If the patient survives the circulatory crisis, he is usually out of danger. After explaining the development of the circulatory impairment, the author points out that the choice of the anesthesia is important. General anesthesia impairs the splanchnic circulation and therefore it is advisable to use local anesthesia. The author thinks that local anesthesia can be used in peritonitis more often than is generally assumed. The exteriorization of the intestine and especially the size of the surgical wound are important factors. The postoperative pain usually increases with the size of the wound, and the greater the pain the greater the impairment of the abdominal respiration, an important factor in the circulation. In discussing the measures for the improvement of the circulation, the author points out that it is a mistake to pay attention chiefly to the heart, for in the beginning it is only secondarily involved, the main problem being to draw the blood away from the splanchnic vessels. In view of this fact, it is not surprising that cardiac stimulants often fail in peritonitis. However, the prolonged withdrawal of blood from the heart is not tolerated for long and therefore it is advisable to introduce more fluid into the circulation; but, since a sudden increase in the quantity is inadvisable, the author recommends continuous drop infusion. In addition to the administration of fluid, vasotonics, particularly adrenal preparations, are helpful. The author directs attention to the influence of the intestinal peristalsis on the splanchnic vessels. He emphasizes the importance of normal respiration for the circulation in the system of the portal vein and shows that carbon dioxide is valuable in stimulating the respiratory center. Application of heat, particularly in the form of sterile fomentations directly on the skin of the abdomen, are helpful.

Epinephrine in Blood in Diseases of Kidneys.—Czeżowska and his collaborators have studied eighteen patients suffering from acute, subacute and chronic glomerulonephritis, pyonephritis, nephrosis and other forms of kidney diseases. They conclude that the content of epinephrine in the blood is increased

in cases of kidney disease with high blood pressure. There is a positive but not wholly parallel relationship between high blood pressure and the degree of hyperepinephrinemia. This observation does not concern patients with general anatomic changes of the organs. There is a relation between the decrease of nonalbuminous nitrogenous substances in the system and increased liberation of epinephrine and arterial hypertension. This connection is made evident through the amount of nitrogenous substances liberated according to whether the disease gets worse or the condition of the kidney improves. The increase of epinephrine in the circulation is not the only or the most important cause of hypertension in diseases of the kidney; hypertension may result from more complicated mechanisms.

Transfusion of Placental and Retroplacental Blood.—

According to Stavskaya, the distinguishing characteristics of the placental blood are high hemoglobin content, increased morphologic elements, considerable bilirubin content, high sugar content, low cholesterol and alkali reserve. The potassium and calcium blood content amounts to from one and one-half to two and one-half times that of normal, while the albumin content of the plasma is lowered chiefly at the expense of the globulins. It contains estrogen, gonadotropic substance and an epinephrine-like substance. It is also distinguished by its rapid coagulability. The author reports the use of retroplacental blood in the obstetric-gynecologic clinic of the Mother and Child Institute in Kiev. The amount of blood obtainable from a retroplacental hematoma varies from 80 to 300 cc. Morphologic and biochemical studies of the placental blood demonstrate its similarity to that of the mother's blood. The iso-agglutinating properties are sharply defined and the blood grouping corresponds always to that of the mother's blood. The blood in vitro shows little tendency to coagulate and may be kept without preservatives for from ten to twelve days. A 4 or 6 per cent solution of sodium citrate was used as a preservative in a series of cases. This blood remained sterile for fifteen days. Placentas expelled later than four hours after the delivery of the child were rejected. Syphilis, malaria, tuberculosis, infectious disease, puerperal endometritis and marked soiling of the vagina were considered contraindications. Only identical blood groups were used. The author enumerates the following indications for transfusion of placental blood: (1) acute anemia due to hemorrhage, (2) puerperal sepsis, (3) cases in which it is desirable to increase the immunity because of anticipated puerperal complications, (4) gynecologic hemorrhages resulting from metropathies or hormone disturbances and (5) preoperative and postoperative period in weakened and exhausted patients.

Weil's Disease.—Blomberg says that the first certain diagnosis of Weil's disease in Finland was made in a man, aged 44. On the forty-third day of the disease, the agglutination test with Weil's spirochete was positive in a dilution of 1:40,000. The manner of infection is not certain. Twenty days before the onset of the disease the patient worked for a day at mend-

ing a water pipe in a cellar infested with rats and with a wet dirt floor. The possibility is suggested that an unbandaged scratch on his thumb may have become infected.

Treatment of Pemphigus Neonatorum. A. Normark.—p. 302.
Influence of Cobra Toxin on Tar Tumors in White Mice. K. A. Vannfält.—p. 315.

Influence of Dextrose on Tar Cancer in White Mice.—Vannfält found that in the mice given a 50 per cent solution of dextrose to drink ad libitum, while the control mice received plain water, metastases of the cancer to the regional lymph nodes was reduced about 50 per cent; the dextrose feeding seemed to lessen the malignity of the primary tumor.

Position of Patients for Electrocardiographic Examination.—Åkesson asserts that in arterial orthostatic anemia, a common disorder, changes in the electrocardiogram similar to those in myocarditis and anoxia of the heart muscle often occur not only when the patient is standing but also when he sits; to avoid differential diagnostic errors, clinical electrocardiography should therefore be carried out with the patient in the recumbent position.

Cancer of Prostate.—Of Kolmert's seventy-five patients with prostatic cancer, largely inoperable, ranging in age from 54 to 83 years, treated at the surgical clinic of the University of Uppsala from 1923 to 1935, eight were living at the end of 1935, and thirty-six of the remaining sixty-seven, or about 54 per cent, had the disease from two to three years or less; the maximum length of life after operation was three and a half years. The author says that cancer should be suspected in cases in which there is burning or pain on urination and short history of disorder without previous troubles of urination. Pain in the back or legs and hematuria are not early symptoms. The metastases are mostly osteoplastic bone metastases in the lower part of the spine, in the pelvis and in the upper part of the femur. Bone metastases also appeared in the cases developed from benign adenomas. Positive diagnosis in the early stages can rarely be made on palpatory results alone, and puncture of the prostate according to Barringer and palpation against the cystoscope according to Young should also be attempted. Twenty-three patients, nearly one third of the material, had metastases on admission; fifteen of these had had urination trouble for only half a year at the most and two had never had any. Twenty-six patients were operated on, half of them with the preoperative diagnosis of hypertrophy; four died in connection with the operation and three from embolism. Metastases or recurrence appeared in 50 per cent of those operated on. Roentgen treatment was extensively used for palliative purposes, partly in the cases in which operation could not be performed and partly in cases in which operation had been performed with recurrence of metastases, and proved superior to other symptomatic treatment.

THE CLINICAL SIGNIFICANCE AND RATIONALE OF MANAGEMENT OF TESTICULAR SWELLINGS

EDWARD WILLIAM WHITE, M.D.

AND

REUBEN B. GAINES, M.D.

CHICAGO

Scrotal pathologic changes in general and testicular swellings particularly offer an open challenge to the medical profession. The clinical picture and correct management is often very baffling, and, while the subject is covered by rather a wide literature, the authors are cognizant of their own limitations and feel that many important phases of the subject are as yet unclarified.

Testicular swelling is of special interest to urologists and general surgeons because it is an accompaniment of different pathologic conditions affecting the testicle itself, and it may apparently be present in pathologic conditions in structures immediately associated with the testicle. The pathologic lesions of the testicle in which there is testicular swelling are infections, both primary and secondary, traumatism and tumors of all types. The pathologic conditions that may simulate a testicular swelling, and from which this must be differentiated, are certain epididymitides, hydrocele, hematocele, infections and tumors of the cord and testicular tunics. We have seen many cases of thickened, chronically infected hydroceles of advanced years that presented a difficult picture for differential diagnosis owing to the grossly endurated tunics and the structural firmness on palpation.

True testicular swelling mostly associated with tumors is generally observed in adults, though it may be seen in infants and the very aged. Certain of the infectious diseases of childhood may cause infectious orchitis, but this, as well as traumatic orchitis, may occur at any age.

When a patient presents himself complaining of a testicular swelling, a complete and thorough medical, physical and urologic examination is of paramount importance. A cursory scrotal and prostatic analysis is not sufficient, owing to the intimate association of testicular pathologic changes and infectious processes in remote organs. Bordet, Wassermann-Hecht blood tests and careful tuberculosis studies must not be omitted.

Assuming that the testicles are normally descended on palpation, the testicle on the side believed to be sound will usually be found normal in size, density and contour. The spermatic cord on the side on which the testicle is apparently swollen should be grasped between the thumb and the forefinger at the external ring and its constituents palpated. If the constituents approximate easily, separated only by the normal parts of the cord,

namely, the vas, the vessels and fascia, one can conclude that the swelling is not a hernia or any other lesion connected with the abdomen and that, therefore, one is dealing with some lesion of the testicle or its adnexa. Of these, commonest by far, is a hydrocele of the tunica vaginalis or of the spermatic cord. The first is pear shaped and blends with the testicle; the latter is globular and lies above and distinct from the testicle. Both are fluctuant and, if recent, both are translucent on transillumination. A hydrocele may be entirely independent and account for the apparent testicular enlargement, or a hydrocele may be a complication of existing testicular swelling. In any case the presence of a hydrocele must be ascertained and, if there is reason to believe that a hydrocele, if present, masks testicular disease, it must be tapped and emptied so that the testicle itself may be investigated. On the other hand, it is well to remember that a rapid testicular cellular growth may present all the characters of a hydrocele except that it cannot be transilluminated. Many diagnostic errors have been made in which testicular neoplasms have been treated as hydroceles. If a hydrocele is found, the testicle should be palpated both during and after its treatment.

If hydrocele can be eliminated, the next step is to investigate for testicular adnexal diseases, namely, hematocele and epididymitides, which simulate testicular swellings. It is difficult to differentiate a long-standing solid hematocele from a testicular neoplasm.

We have in our records five cases of hematocele of long standing which were only with difficulty differentiated from testicular new growths. The following report will illustrate the confusion often existing between hematocele and testicular sarcoma:

M. S., a man, aged 52, entered the urologic division of the Alexian Brother's Hospital, Chicago, April 10, 1930. The history in brief consisted of a weird narrative of excessive sexual attempts, sexual failures and unnatural sex practices covering a period of forty-eight hours. Within eight hours following the foregoing experiences, we were informed, he was taken with sudden acute agonizing pain in the left testicle and left inguinal region, temperature rises, nausea, vomiting and extreme shock. He was not a local resident and had been elsewhere, and our knowledge of the case came approximately ten days following the appearance of symptoms. Previous diagnosis of hematocele had been given following puncture of the tunic, and none had considered the possibility of testicular tumor. An orchidectomy was performed April 22, and a diagnosis of small round cell sarcoma was obvious following pathologic studies. Extreme radiotherapy was instituted but the patient died five and one-half months later of metastases to the lungs and liver.

This history is instructive, and one is impressed with the seriousness of these cases, the sudden onset and the difficulties encountered in diagnosis.

Tanner¹ says that if on the surface of a scrotal tumor one palpates the tunica vaginalis it is certain that one

1. Tanner, C. O.: Tumors of the Testicle, Surg., Gynec. & Obst. 35: 565 (Nov.) 1922.

is not dealing with a hematocele. It is also impossible in hematocele to feel the epididymis between the fingers, because it is hidden in the cavity of the hematocele. There are, however, certain signs that will help one in recognizing a hematocele: History of a local traumatism is significant; transillumination of the scrotum is not possible; testicular sensation is often lost; it is difficult to distinguish the testicle from the epididymis; the swelling is usually round, solid and hard in consistency and about the size of a duck's egg; in weight, the tumor gives the impression of being heavy; the spermatic cord is often thickened; the layers of the tunica vaginalis cannot be felt by palpating between the fingers. Needle puncture for blood in hematocele is useless as a diagnostic measure, and it may be dangerous.

With the exclusion of hematocele and hydrocele, our quest is reduced to a lesion of the epididymis or of the body of the testicle. An enlargement of the epididymis is usually not of malignant nature but is an inflammation of tuberculous or pyogenic origin. According to

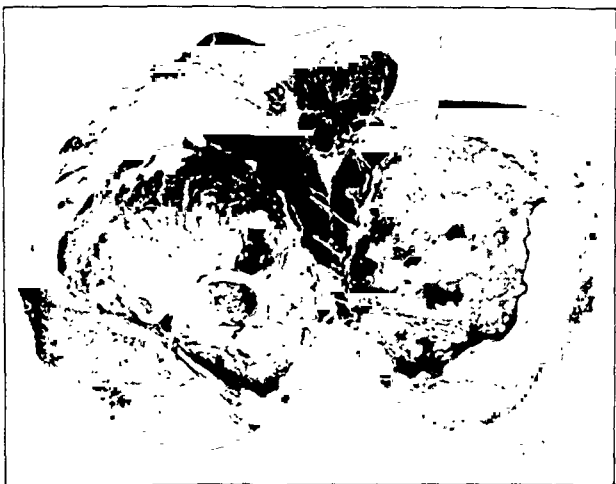

Fig. 1.—Chronic inflammatory hydrocele. The testicle is moderately atrophic with no evidence of spermatogenesis. The capsule is thickened and densely fibrous nearest the testicle itself. Zones of scar tissue covered by purulent exudate are found throughout the testicle.

Mark,² while tuberculosis of the epididymis is known to be relatively common, a critical study of the literature as well as the replies to a questionnaire elicited the fact that primary tuberculosis of the testicle does not exist or is exceedingly rare. If the swelling being investigated is an epididymal tuberculosis, one may reasonably expect nodular areas alternating with caseating areas and nodularities of the vas. If the epididymal swelling is of pyogenic origin, one might expect a tender prostate and seminal vesicles or inflammation about the urethra or bladder neck. If one is unable to find any of these signs, one is justified in concluding that the swelling is due to a lesion of the body of the testicle and that the possible lesions are infections including syphilis and tuberculosis, traumatism or tumor.

TESTICULAR SWELLINGS NOT ASSOCIATED WITH TUMOR

Infections.—Regarding testicular swellings due to infections, Wesson³ says that inflammation of the testis without a coincident prostatitis and seminal vesiculitis

indicates a blood-borne infection. Almost any organism in the blood stream may enter the testis and, if there is a lowered resistance of the gland or an abundance of infective organisms, a foothold may be gained and characteristic lesions produced. However, the rule is that organisms that have invaded the general circulation are rapidly filtered out so that, as far as the testicle is concerned, blood-borne infections are fairly rare. Acute infectious orchitis may occur as the result either of bacterial invasion or of bacterial toxemia; the type example of hematogenous orchitis is seen in mumps, typhoid, pneumonia and smallpox.

Besides the blood stream, testicular infection may occur through the lymph channels and through the natural communications with the vas deferens, epididymis and other associated structures. Localization of bacteria may follow injuries to the cord or operative interventions and spread by contiguity to the testis. It has been alleged that, following a strain, *Bacillus coli* from an infected urine spread to the testicle. In 1927 Caulk⁴ found testicular abscess in 5 per cent of patients with epididymitis; also two cases in which testicular abscess developed after hydrocele operations. Mathé⁵ himself reported two such cases following epididymectomy. He thinks that a great many testicular infections are classed as epididymitides and that cases of gonorrheal orchitis, if on the right side, may be taken for appendicitis. Although suppuration is rare and most of these cases recede without atrophy of the testis, there may be considerable sloughing with ultimate destruction of the testicle. Mathé reports a case of suppurative orchitis due to the colon bacillus in a young man following instrumentation in which an orchidectomy was necessary. A similar case was reported by Grön and Thjotta.⁶ A progressive testicular swelling was one of the important diagnostic points in these cases. Cases of suppurative orchitis following instrumentation are quite common but fail to reach the literature. Our records give seventeen cases of testicular abscess covering a period of twenty years, twelve of which required orchidectomy.

Tuberculosis.—According to Dean,⁷ tuberculosis is a factor in less than 10 per cent of testicular swellings. Mention has already been made concerning tuberculosis in the epididymis. A general tuberculosis first spreads to the genital organs by way of the epididymis, then extends along the vas and finally to the testicle. The family and personal history of the patient should be of value and roentgenograms might show active tuberculous lesions in the lungs. Rectal palpation should disclose any involvement of the prostate and seminal vesicle.

Wesson³ states that the presence of tubercle bacilli in the seminiferous tubules of the otherwise healthy testes in tuberculous subjects is no longer accepted. Before a tuberculous epididymitis or orchitis can be attributed to a contusion, two conditions are necessary: the blood must be filled with tubercle bacilli from an infected focus and at the same time the testis or epididymis must be anatomically so injured that the site provides a suitable culture medium for the settlement of the tubercle bacilli from the blood stream. Trauma as a cause of tuberculous orchitis must be extremely rare. On the other hand, a tumor develop-

ing in the testis may extend from the rete testis into the epididymis and simulate tuberculosis or into the vas deferens and suggest tuberculous thickening of the vas in subjects who give a history of tuberculosis.

Syphilis.—In a testicular swelling due to syphilis, testicular sensation is lost; the consistency of the swelling is often hard and solid in early syphilis, the swelling approximates the size of a pullet's egg, it may be ovoid, globular or pear shape, and its weight appears light. The spermatic cord is rarely thickened and the layers of the tunica vaginalis may sometimes be felt by palpation. A positive Wassermann reaction is not diagnostic because it may be given in other conditions; however, other things being equal, a testicular swelling due to syphilis ought to diminish in size after from four to eight weeks of intensive antisyphilitic treatment.

It should be remembered that a malignant tumor of the testicle and syphilis of that organ may coexist; also that the testicle and epididymis may be distorted by masses of tumor tissue which closely simulate gummatous lesions of the testicle.

Traumatism.—Traumatic Orchitis: Wasterlain⁸ cites the view of Chevassu in relation to trauma and swelling of the testicle; namely, that the trauma must be manifest; it must consist of a painful swelling of the scrotum with blood extravasation, and there must be a free interval of several months between the accident and the appearance of the testicular tumor.

Bollag⁹ reported two cases of tumorous swelling of the testicle apparently due to injury. The first patient, aged 48, had worn a truss since childhood for hernia of apparently traumatic origin. A carcinoma simplex (seminoma) resulted. The other patient, a man aged 20, fell from a bicycle, injuring the left testicle; a malignant mixed tumor of the testicle developed shortly after.

Many authors cannot conceive the possibility of an orchitis brought on by strains, although cases have been reported of testicular infection by *B. coli* alleged to be due to strain when the infected bladder was full. It is perhaps possible that injury to an infected hydrocele may spread the infection to the testis.

Wesson³ analyzed seventy cases of reputed traumatic orchitis reported in the literature and states that in no instance was there an atrophy of the injured testicle. In five cases atrophy had followed a previous orchitis. The majority of the cases were nonvenereal epididymitis or tuberculous epididymitis. Only three cases were possibly due to trauma, two hematoceles and one torsion of the spermatic cord. Wesson points to the fact that university and other athletes who are subject to unusual strains do not develop orchitis. He is of the opinion that seminal vesiculitis and not contusions or strains is responsible for the epididymitis commonly diagnosed as "traumatic orchitis."

Simple contusions of the testicle rupture small vessels with resulting hemorrhagic points. The pressure of the tunica vaginalis controls the bleeding. There may be edema and the testicle may become enlarged and hard. Fibrosis may follow at points of injury. If there is extensive cicatricial contracture there may be eventual atrophy of the testicle.

We feel that in true trauma of the testis either there are constitutional symptoms, such as nausea, vomiting, great weakness, fainting and evidence of extreme shock, occasionally resulting in death, or there is local evidence of injury such as extravasation of blood with resultant

pain, loss of function, with swelling beneath the deep fascia and discoloration, which appears promptly because of injury to the superficial structures.

We have observed that in many cases of testicular tumors the patient gives a history of trauma suggesting that the tumor was the result of traumatism, but usually the injury has only called attention to a testicular swelling which had been existing for a period of time. In spite of the number of cases in which there has been a history of trauma, it is, however, doubtful whether trauma gives rise to any neoplastic process. In two of the thirteen cases of testicular tumor reported by MacKenzie and Ratner¹⁰ the patients gave a history of trauma less than a year previous to the appearance of scrotal swelling.

TESTICULAR SWELLINGS ASSOCIATED WITH TUMORS

On account of their clinical importance and comparatively far greater frequency, testicular swellings in association with some type of testicular tumor are of much more practical interest than testicular swellings associated with other conditions. If, following the localization of such a swelling of the testicular tissue proper, infection and trauma can be ruled out, there is no other alternative but a diagnosis of testicular tumor. Formerly all such tumors were considered to be sarcomas and highly malignant; later they were classified into four or five groups, but the accepted view today is that a great majority of tumors of the testicle are of embryonal origin.

All authors agree that in the etiology of such tumors neither heredity, occupation, race nor environment plays any part. More than 95 per cent of testicular tumors originate from aberrant sex cells. New growths may arise from any type of such cell present in the testicle which contains, potentially, the three germinal layers (epiblast, mesoblast and hypoblast). Pathologists tell us that, therefore, any type of tumor—connective tissue, epithelial or mixed type—is possible. There are homogenous and heterogenous tumors and, in each, there may be benign and malignant types. They may be found in either normally descended or ectopic testicles.

Testicular tumors are not rare. Desjardins and his associates¹¹ report on 155 such tumors observed in the Mayo Clinic between 1920 and 1929 and they as well as others have found that, although such tumors may

be observed at any age, they are mostly a development of the period of active sex life. That many cases of testicular tumors are not correctly diagnosed is obvious.

CLASSIFICATION AND TYPES OF TESTICULAR TUMORS

There is some variance of opinion concerning the classification and types of testicular tumors. As stated already, the vast majority of these were considered as sarcomas. In 1906 Chevassu¹² published a classification, which was generally accepted until recently. This comprised six classes, of which three were specific; namely, (a) the seminal epithelioma or seminoma developing in the interior of the testicle by proliferation of specific cells lining the seminal tubules; it is a solid, fleshy, homogeneous tumor metastasizing probably through the lymphatics; (b) tumor of the interstitial cells, a specific tumor occurring rarely and mostly in ectopic testicles; (c) the specific testicular adenoma,

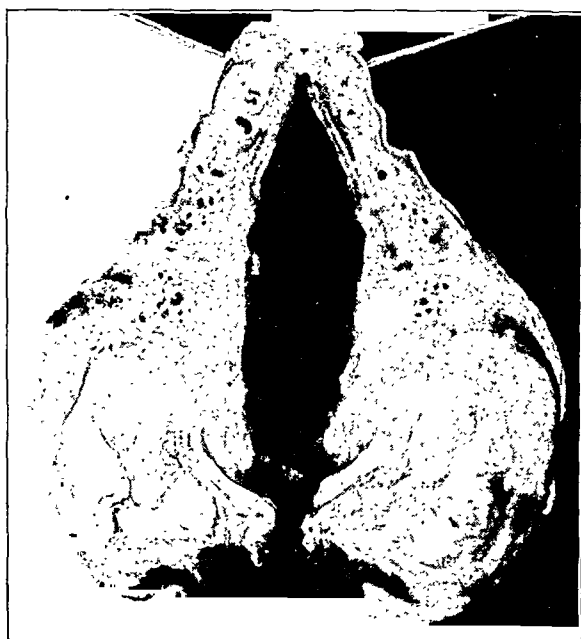

Fig. 3.—Central abscess of the testicle. The central abscess is here clearly indicated. The central necrotic mass can be seen, also the point at which it broke through to the outer coverings of the testicle.

also more frequently seen in ectopic testis. Among the nonspecific testicular tumors Chevassu included (d) the fibroma, arising from the fibrous tissue of the testicles and of which only a limited number of cases have been reported; (e) true primary sarcoma, usually small round cell sarcoma. Chevassu considered this type rare, having seen it only in one of 126 cases of testicular tumor. Most writers now agree that true primary sarcoma of the testis is rare; (f) finally, Chevassu described the mixed tumors, the embryomas, containing both epithelial and connective tissue.

Ewing¹³ advanced the view that all malignant tumors of the testicle were of embryonic origin and were therefore teratomas. He considered that Chevassu's seminoma was only a particular type of teratoma and that it was not developed from adult spermatoblasts but, like the mixed tumors, arose from aberrant sex cells that contained all three germinal elements. While many writers still retain the term seminoma, opinion is tend-

ing toward a general acceptance of Ewing's theory that all testicular malignant tumors are teratomas.

Morton¹⁴ made a pathologic study of tissue from 102 cases of testicular tumor seen at the Mayo Clinic up to the end of 1927. The most common type (sixty-nine out of 102) was carcinoma simplex or malignant seminoma; there were twenty-eight embryonal teratomas (mixed tumors), three fibrosarcomas and two dermoids.

Most writers agree that malignant testicular tumors are mostly embryonic carcinoma or embryonic teratomas. Herger and Thibaudau¹⁵ made a histologic study of fifty-six out of sixty-three cases of testicular tumor observed during the past twenty years in the New York State Institution for the Study of Malignant Disease and found that fifty-five were teratomas and one was a fibrosarcoma.

Chorio-epithelioma, similar to that found in the female genitalia, is occasionally found in testicular tumors. Fortner and Owen¹⁶ recently reported two cases in adults; Entwisle and Hepp¹⁷ in 1935 reported a case in an adult and stated that 131 cases of chorio-epithelioma in males had been reported up to 1932. This tumor was first described by Schlagenhafer in 1902. It is stated generally that tumors of the ovary are more benign than similar tumors in the testicle and, when malignant, are less malignant.

Only a small percentage of testicular tumors are benign. Tanner¹ states that among the benign tumors there are dermoids, adenomas of the seminal tubules, interstitial cell tumors, fibromas, lipomas, myomas and chondromas. Examples of each have been reported in the literature. Stewart, Bell and Roelke¹⁸ recently reported a case of interstitial cell testicular tumor in a boy aged 5 years.

Among the rare types, Jenkins and Deming¹⁹ describe simple cysts of the testicle which they differentiate from cystic neoplasm and encysted hydrocele.

TUMORS IN UNDESCENDED TESTICLES

In 1921 Cunningham²⁰ found new growths over ten times as frequent in normally descended as in undescended testicles. But many urologic surgeons are of the opinion that an undescended testicle is more likely to develop a primary tumor than a normal one. About one in every 253 male hospital patients show undescended testicles. Hinman and Benteen²¹ in 1936 stated that 160 cases of testicular tumor in cryptorchids had been reported. The incidence of tumor arising in cryptorchidism is reported as varying from 11 to 15 per cent by different authors. Dean found that malignant tumor occurred in 14.28 per cent of undescended testicles. Higgins²² found that malignant disease occurred three times in 251 cases of undescended testicles; three of his sixty-six malignant tumors were in undescended testicles, two in the inguinal canal and one in the abdomen.

Hinman's²¹ personal study, based on the observation of 40,000 male hospital patients in the California Hospital, showed that testicular tumor occurred twenty times more frequently in undescended than in those normally descended. Dean found that teratoma occurs about 237 times as frequently as in normally descended testicles.

An abdominal tumor of testicular origin obviously presents many formidable problems of differential diagnosis. It is a rapidly growing process, not infrequently inoperable, and the end results are generally unsatisfactory.

INCIDENCE OF TESTICULAR TUMOR

Hinman and Benteen,²¹ based on the study of nearly 40,000 male hospital admissions, found the incidence of testicular tumors as about one in 983 patients. Tanner¹ and Carlton²³ estimate that a testicular malignant condition is seen in about one in 2,000 males seen in the average outpatient department. According to Dean,²⁴ based on the admissions to the Memorial Hospital in New York, between 1917 and 1926 testicular malignant growths comprised 3.39 per cent of all tumors of the genito-urinary system, 2.09 per cent of all malignant tumors in the male. The average age at which the tumor becomes manifest is 31.7 years but it may be seen at any age. In MacKenzie and Ratner's¹⁰ series of cases the ages varied from 21 to 64 years. In Higgins's²² sixty-six cases the average age was 34.

Regarding laterality, most writers agree that the right testicle is more frequently affected than the left and, according to Dean,²⁴ the right testicle is the site of 52.2 per cent. Bilaterality is very rare; Higgins noted it in one out of sixty-six cases.

According to Tanner,¹ 96 per cent of new growths of the testicle are malignant.

Testicular tumors are rarely observed in children. Higgins states that the largest series collected in children contained only forty-two cases.

SYMPTOMS OF TESTICULAR TUMOR

Patients with swellings definitely located in the testis should be thoroughly examined and all diagnostic tests, especially the hormone test, which will presently be referred to, applied.

There are no pathognomonic symptoms of malignant testicular tumor, and experience has taught us that the symptoms of testicular tumor in general are most uncertain. Some patients complain of a mass in the scrotum or groin accompanied or not by dragging pain; others may mention occasional shortness of breath, cough or swelling of the legs. As a general rule, in the early stages of testicular swelling there is no pain, according to our observation and those of others, the initial symptom in 75 per cent of cases of teratoma being a painless swelling of the testicle. After pain is felt, metastases are usually rapid. In Higgins's series of sixty-six patients, 18.1 per cent complained of testicular pain and thirty-one per cent complained of more or less lumbar pain. Pain may be elicited on palpation of the testicle. As a later manifestation of a malignant growth, 27 per cent noted loss of weight and 26.4 per cent loss of appetite. In the majority of cases there is a progressive enlargement of the testicle with freedom from pain until metastases can be demonstrated clinically. We have commonly noted that in the early

stages of a malignant condition the testicle is firm and smooth with no change in contour. Nodulations may occur later. The epididymis is usually unchanged and free from manifest pathologic changes, the skin moves freely over the testicle; the scrotum cannot be transilluminated.

Clinically the symptoms may be divided into three periods: the period of onset when the testicle is still in the scrotum, the period of evolution when the gland reaches considerable proportions, and the final period, characterized by grave symptomatology with infection of all lymphatic nodes of the lumbo-aortic region and cord.

We have been impressed with the rapid advancement of these abdominal testicular tumors and the delayed appearance of these patients in seeking medical or surgical aid. Time is an ever important factor and in the two cases seen by us the growths had advanced to the size of the fetal head with fatal terminations six months and eighteen months following an attempt at surgical assistance.

Fig. 4.—Seminoma. Practically all the mass is tumor tissue composed of round, oval or polygonal cells with large vesicular nuclei. The cells are crowded together in irregular masses separated by thin bands of connective tissue stroma. The tumor has involved the epididymis. Areas of necrosis are large and numerous.

DIAGNOSIS OF TESTICULAR TUMORS

As already stated, there are no clinical pathognomonic symptoms of testicular tumors. The clinical diagnosis is made chiefly by exclusion. As Cieza Rodríguez and Mainetti²⁵ show, a testicular tumor may be masked by a greatly thickened tunica vaginalis or by epididymitis or by a tuberculous lesion of the testicle. We also note some presumptive physical signs, which are significant; testicular sensation is sometimes lost, in malignant disease the consistency is sometimes hard and solid and, as regards weight, the testis seems heavy. The tumor may be ovoid, globular or pear shaped, and the size is usually that of a fowl's egg. The spermatic cord is usually thickened in malignant disease; layers of the tunica vaginalis can be compressed with the palpating fingers easily. If there are metastases, nodules can be felt in the cord and mass along the lymphatics.

The introduction of biologic tests in recent years has greatly simplified the diagnosis of malignant tumor of the testicle and its differentiation from benign tumors. This method, which was developed by Ferguson,²⁶ cut-

ler and Owen,²⁷ Zondek²⁸ and others, gives a means of determining the presence of metastases before they make their clinical appearance, as well as of detecting any hidden extensive metastases that may have resisted radiation treatment. There is thus a biologic as well as a clinical method of determining the presence of metastases. MacKenzie, Ratner and others point out that in testicular malignant neoplasm metastases occur very early and are often present in cases in which clinically they cannot be determined. They spread first by the lymphatic route to the lumbar glands and to the glands along the spermatic vessels and later to the retroperitoneal glands. By the blood route metastases may travel quickly to the lungs, liver and other viscera.

The biologic test consists in the observed fact that the urine of patients with embryonal tumors contains a notable amount of gonadotropic hormone. Cutler and Owen²⁷ made quantitative determinations of the follicle

Fig. 5.—Malignant teratoid in undescended testicle. This specimen is the size of a fetal head, as stated in the text. It is characterized by the typical teratoid tumor mass with a multitude of small cysts scattered throughout.

stimulating factor in the urines of sixty-six patients with teratoma of the testis; also in thirteen normal men and patients with benign testicular tumors. In all the latter the amount of the hormone was less than 50 mouse units; in the first group it varied from 50 to 16,000 mouse units per liter of urine.

The test with the follicle stimulating factor is positive in 60 per cent of testicular tumors independent of the nature of the tumor. The value of reaction in male cases is increased by the fact that it is negative in many other disorders of the male genitalia, such as, for instance, carcinoma of the prostate.

It should be noted, however, that a positive hormone test is not pathognomonic of testicular embryonic tumor; it may be given in the presence of an embryonal tumor elsewhere. Furthermore, pure specific testicular tumors may give a negative test. A pure seminoma may not cause excretion of increased follicle stimulating factor in the urine.

The hormone excretion test is valuable in determining the presence or regression of metastases. Patients in whom at operation no metastases have been found usually fail to excrete hormone within two weeks after orchidectomy. If the hormone persists there are usually hidden metastases. Also a local recurrence of tumor or metastases is generally preceded by a rise in the quantitative excretion of the hormone in the urine. This is a valuable method of checking the necessity or not for more radical measures in the surgical treatment of malignant testicular tumors. The hormone test appears to give a fairly accurate method, in association with clinical changes, of estimating the presence or absence of a testicular malignant condition. It makes diagnosis possible before the malignant growth has extended beyond the testis and before extensive metastases have rendered the case inoperable or helpless.

TREATMENT OF TESTICULAR TUMORS

There are now three recognized methods of treating testicular tumors: (a) simple orchidectomy, (b) irradiation with or without castration, and (c) the radical operation, in which the testicle and its primary and perhaps secondary lymph zones are removed.

In considering the important question of surgical intervention in testicular malignant growths we feel that our personal reaction and views have experienced a severe upheaval since the advent of gonadotropic hormone estimations. Some authors are of the opinion that surgery must be limited to those cases in which there is no clinical or biologic evidence of a malignant condition before or during operation. In our series of cases prior to 1932, surgery had been advised in almost all instances, to be followed by thorough and intelligent irradiation both locally and generally. Radiologic and biologic advancements have materially broadened our views in this matter; now, with the advantage of a more concrete and exacting classification of tumors, degrees of malignancy and radiosensitivity, surgery is advised only in the cases that show no clinical evidence of metastases and low hormone titers. The foregoing is a brief citation and is modified in keeping with the severity of the case and the entire clinical picture presented. Intensive radiotherapy and early orchidectomy is our rule.

ORCHIDECTOMY

Orchidectomy in its simplest form and with the exclusion of all wide spreading glandular extirpation is advocated. In the light of modern radiologic therapy, extensive surgical procedures are not only futile but practically unnecessary. It is important to remember that a wise procedure in an orchidectomy is to sever the cord before the tumor is handled in any way. This will help to prevent the possibility of having any malignant cells thrown into the lymph or blood stream. It is further generally conceded that great care should be taken in every operation on the testicles to prevent operative inoculations; neoplasms of the testicle are very fragile and should be traumatized as little as possible.

Higgins²² believes that radiation should be administered to the testicle and inguinal glands prior to orchidectomy, the operation being performed from two to three weeks later. There should be systematic irradiation of the same and the lumbar glands following orchidectomy. Preliminary irradiation has been carried out by us and no appreciable change in end results was noted.

RADIATION

Experience with radiation shows a great difference in the degree of sensitivity of various types of testicular tumors to this mode of therapy. Desjardins²⁹ says that the cells of the testis most sensitive to radiation are those which form the basal layer of the tubules, which are known as spermatogonia. The spermatocytes, which are more mature, are not nearly as sensitive. Pure seminomas and homogeneous embryonal carcinoma are radiosensitive and, if hormone tests disclose a tumor of such type without metastases, irradiation without surgery may be tried.

Only with considerable hesitancy do we rely solely on radiation for the treatment of a primary testicular tumor. Its growth may be temporarily restrained, but it may be responsible later for the dissemination of metastases; there is also the danger to the opposite testicle from intensive irradiation to the affected one.

Desjardins and his associates¹¹ report on the result in 155 cases of testicular tumor treated at the Mayo Clinic between 1920 to 1929 by orchidectomy both with and without irradiation. Seven patients, all seen in the first years of the disease, were treated by orchidectomy alone; twenty-three were treated by roentgen rays alone; 125 were treated by the combined method. Of the second group 56.6 per cent were seen during the first year, and of the third group 76.1 per cent were seen during the first year. Of the first group three, of the second group seven, and of the third group sixty patients were alive and well at the time of reporting (1935). The authors conclude that patients receiving combined treatment derive more benefit than patients treated by surgical methods only or by radiotherapy only. The results of radiotherapy depend largely on the stage of the malignant process, particularly if metastases have not spread beyond the para-aortic lymph nodes in the lumbar region.

Hinman,³⁰ analyzing 258 collected cases in which orchidectomy with or without irradiation was the mode of treatment, found that 118 patients were dead and 124 were living, but only seventeen for five years or more, a cure of only 6 per cent. In inoperable cases high voltage roentgen treatment of abdominal metastases showed only a few successes.

RADICAL OPERATION

The first complete radical operation for malignant testicular tumor was carried out by Roberts³¹ in 1902. Following operation he removed the retroperitoneal lymph nodes along the abdominal portion of the aorta. At the present time Hinman³⁰ is the strongest advocate of this method of treatment. Keyes,³² reporting in 1926, was not enthusiastic about the radical operation and believed that its execution was possible in only a little over 50 per cent of cases. In 1933 Hinman³⁰ reported that more than 100 radical resections had been carried out by himself and other American surgeons with only one operative fatality, so that the operation was entirely feasible. On retroperitoneal exposure twenty of these 100 cases were found to be inoperable. The operation was completely carried out in the remaining eighty cases. In the eighty, no metastases were found in thirty-six; eleven of these patients were alive five years or longer; of the entire eighty patients on

whom a complete radical operation was done, 35 per cent were dead from metastases and 63.75 per cent were alive, seventeen patients (20.1 per cent) for five years or more.

In a later report Hinman³³ pointed out that anything short of complete removal of the primary and immediate secondary lymph nodes was not a true radical operation. This was possible only on the right side owing to the superior mesenteric artery on the left side. However it might be possible to remove the left lymphatic areas if approach to them was made from the right side.

Taking into account intensive irradiation and the present status of hormone estimations, we note that in an analysis of some forty-five cases of testicular neoplasms thirty presented no clinical evidence of metastases when first examined. In the remaining fifteen cases secondary involvement was definitely established on presentation.

In the thirty patients with no apparent metastases, twelve received radical surgery and all presented micro-pathologic sections of glandular metastases; however, eight of the patients in this bracket carried on from two to seven years after operation. The remaining eighteen patients were given simple orchidectomy, ten with irradiation and eight without, with an average of longevity of from two to five years respectively.

Fifteen patients with clinical evidence of metastases were treated by orchidectomy and high voltage x-ray exposures; all gave a fair or poor prognosis and those followed up all had succumbed in from six months to three years following.

We are all in accord that cases of teratoma without a suspicion of metastases, being radioresistant, offer the best types for radical surgery. It should be remembered that patients without clinical evidence of metastases may after orchidectomy show by hormone tests that metastases are present and in such cases radical procedures may be justifiable, if one is inclined to be radical.

The prognosis, as the result of the present day conception of the rationale of tumor management, is vastly more encouraging, yet the end results in our experience, although more delayed, are ultimately fatal.

CASTRATION PLUS SERUM TREATMENT

Coley's³⁴ serum treatment of testicular tumor should be mentioned. In 1923 he reported seventy-eight cases presenting metastases treated by orchidectomy followed by injection of serum (toxins). Of the seventy-eight patients, twenty-two survived four years or more.

PROGNOSIS OF TREATED TESTICULAR TUMORS

The prognosis in the case of a testicular tumor, treated surgically or by surgery combined with irradiation, has greatly improved within the past ten years. Keyes,³² writing in 1926, says: "I have seen approximately thirty patients afflicted with this disease (malignant testicular tumor) and with one exception, under the surgical treatment exclusively employed up to about ten years ago, I have not known a case to survive three years from the time the diagnosis was made and the testicle removed." However, Keyes cites Handfield-Jones, who reported twenty-two cases of simple orchidectomy without abdominal operation with eleven survivals for a considerable time, four of these for four

years or more. In Tanner's¹ 600 cases collected from the literature, nearly all treated by orchidectomy alone, only twenty-five patients (5.5 per cent of those followed) were living and well four years or more after operation, representing a mortality of 36 per cent. The operative mortality at the present time is practically nil.

Regarding radiation treatment alone, Dean⁷ states that in a series of 170 patients with teratoma, 72 per cent of whom had metastases, the five year end results after irradiation show 29 per cent of the men living and well and free from disease.

Regarding the results following orchidectomy with irradiation of the lymph-bearing area, Herger and Thi-baudau¹⁵ state that 33 per cent of their twenty-one patients survived for three years or longer. MacKenzie and Ratner¹⁰ give the operative mortality of the radical operation as varying from 10 to 20 per cent. Hinman²³ gives it as approximately 11 per cent.

The date of onset, the hormone estimation, radio-sensitivity and tumor types must be carefully studied in all cases of testicular swellings.

55 East Washington Street.

BLOOD GROUPING AND COMPATIBILITY

A SIMPLE TECHNIC FOR DETERMINATION FROM SMALL AMOUNTS OF DEFIBRINATED WHOLE BLOOD

PAUL HOXWORTH, M.D.

AND

AZEL AMES, M.D.

CINCINNATI

In municipal hospitals heavily burdened with traumatic surgery, the method employed for grouping and matching blood prior to transfusion must be chosen for speed as well as for accuracy. While meeting modern requirements for safety, the technic will of necessity be designed primarily for efficiency. At the Cincinnati General Hospital, where more than 500 transfusions are given each year in the surgical service alone, there has been a gradual evolution toward a more efficient routine for the selection of donors from groups of unknown volunteers. The procedure that we now consider ideally suited to our needs is a combination of the Vincent¹ open macroscopic method for grouping and the Coca² compatibility test for direct matching. Each method has been slightly modified, so that both determinations may be made with a single small sample of defibrinated whole blood. The Vincent and the Coca methods were reported almost simultaneously in 1918. We know they were used in combination for many years by Coca and Grove at the New York Hospital prior to 1932, and perhaps others have employed both methods; but the advantages of their use in combination have never been emphasized, and the Coca compatibility test is known to very few.

Prior to 1918 the best methods for grouping and direct matching were those advocated by Minot.³ He

pointed out the need for simple rapid methods, did away with the washing of cell suspensions, and encouraged elimination of the old hemolysis tests established by Moss⁴ and Epstein and Ottenberg⁵ and later modified by Weil⁶ and by Rous and Turner.⁷ For blood grouping he advised the use of stock test serums and a simple citrated blood suspension (one drop of blood in 1 cc. of a 1.5 per cent sodium citrate solution in saline solution) mixed in cover slip preparations. For direct matching he advocated Weil's⁶ 1:9 and 9:1 mixtures of citrated whole blood set up in tubes but read microscopically in hanging drop cover slip preparations. The contingencies of war led to the development of a rapid macroscopic agglutination⁸ test for blood groups by Vincent, who found that, by citrating stock test serums, blood could be added directly from finger puncture to drops of serum on a slide.

In the hands of experienced technicians employing standardized high titered test serums, the Vincent method is now generally considered the safest as well as the simplest procedure for determining blood grouping. If the selection of donors could be rigidly restricted to a choice of individuals from the same blood group as the patient, no further test of compatibility would be required except as a check for possible errors in grouping and the exceptional occurrence of atypical agglutination. In emergencies, however, just as one must sometimes employ a donor without knowledge of his Wassermann reaction, relying on an examination for primary and secondary lesions,⁹ so must one also at times make use of a "universal" donor or, more rarely, in the case of a "universal" recipient, a donor from group A or B. Under these circumstances a compatibility test is imperative, for it is well known that group O¹⁰ donors frequently possess agglutinins of a titer dangerous for A or B recipients,¹¹ even in the proportions of a small transfusion. Furthermore, compatibility must be determined quantitatively as well as qualitatively by some method that will reproduce as faithfully as possible in vitro the conditions (whole blood) and proportions of the proposed transfusion in vivo. Therefore it is quite essential in hospitals of this type that the method employed for direct matching be designed not only for checking grouping errors and atypical agglutination but also for actual slide titration

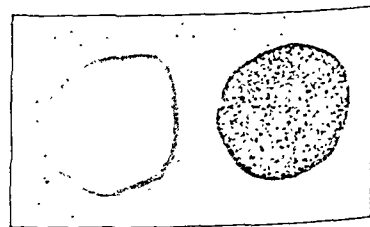

Fig. 1.—Group A agglutination fifteen seconds after blood was mixed with serums.

of the donor's agglutinins against a proper proportion of the patient's blood. Coca's method, simplifying the older methods of Weil, and of Rous and Turner, and

modified by Levine and Mabee¹² and Landsteiner,¹³ admirably fulfils these requirements.

TECHNIC

Approximately ten drops of blood is obtained by finger puncture and defibrinated in a Wassermann tube by whipping with a wooden applicator for five minutes. This quantity is sufficient for grouping and several compatibility tests. Separation of cells and serum is not desirable.

Grouping.—Large drops of high titered test serums anti-B and anti-A are placed on the left and right ends respectively of a glass slide. Defibrinated blood is added to each drop of serum and thoroughly mixed with the aid of a platinum loop. The slide is tilted back and forth over a white background in bright light and observed macroscopically for clumping. Agglutination is striking (fig. 1) and, if serum of grade I (Coca¹⁴) is used, will be complete in less than one minute. When no agglutination is seen after one minute on either side, the slide is placed under a petri dish with wet blotting paper and observed again fifteen minutes later as a precaution against weak agglutinogens.

Matching.—A 1:1 or 50 per cent suspension of the recipient's defibrinated blood is prepared in the stem of a white blood cell counting pipet by drawing blood up to the 0.5 mark and then filling to the 1.0 mark

Comparison of Agglutinin Titer of Serums Used at Cincinnati General Hospital with Grade I (Coca) Serum

Serum	Serum Dilution	Cell Dilution	Macroscopic Agglutination Time
Grade I (Coca).....	1-4	1-4	11 seconds
Serum at Cincinnati	Anti-A 1-10	1-4	5 seconds
General Hospital	Anti-B 1-10	1-4	5 seconds

with physiologic solution of sodium chloride. The blood is diluted 1:1 with saline solution because agglutination cannot be differentiated microscopically in any greater concentration and because dilution inhibits undesirable rouleau formation. The diluted blood is deposited on the left end of a glass slide and mixed by means of a jet of air blown from the pipet. An identically prepared suspension of donor's defibrinated blood is placed on the right end of the same slide, and one fifth of this drop (two divisions of the pipet) is transferred to the drop of diluted recipient's blood. This 1:5 ratio is based on the assumption that 500 cc. is to be transfused to a patient whose blood volume is depleted 50 per cent, or approximately to 2,500 cc. It provides a wide margin of safety in transfusions from a "universal" donor, as dangerously potent agglutinins will not be completely absorbed in this concentration without manifest agglutination.¹² The 1:5 mixture of donor's and recipient's blood is then stirred with a platinum loop or glass rod, and the slide is placed under an inverted petri dish with a piece of wet blotting paper. After fifteen minutes the mixture is again agitated and observed microscopically under low power for agglutination.

Care must be taken not to confuse rouleau formation with agglutination. The former can always be broken up by stirring, while the latter will be intensified. Agglutination will be striking if a grouping error has

been made (fig. 2), but a little practice is required to estimate the degree of agglutination of the recipient's cells by a "universal" donor's agglutinins, in the presence of nonagglutinable cells forming rouleaux. Unless the agglutination is so definite and conspicuous that there is no question of confusion with rouleau formation, the blood may be pronounced compatible.

DATA

The importance of employing reliable standardized high titered test serums cannot be overemphasized. Open macroscopic grouping methods require an abundant supply of such serums. Before undertaking experiments with the Vincent method, we prepared large quantities of anti-B and anti-A serum from the blood of two volunteers possessing unusually high

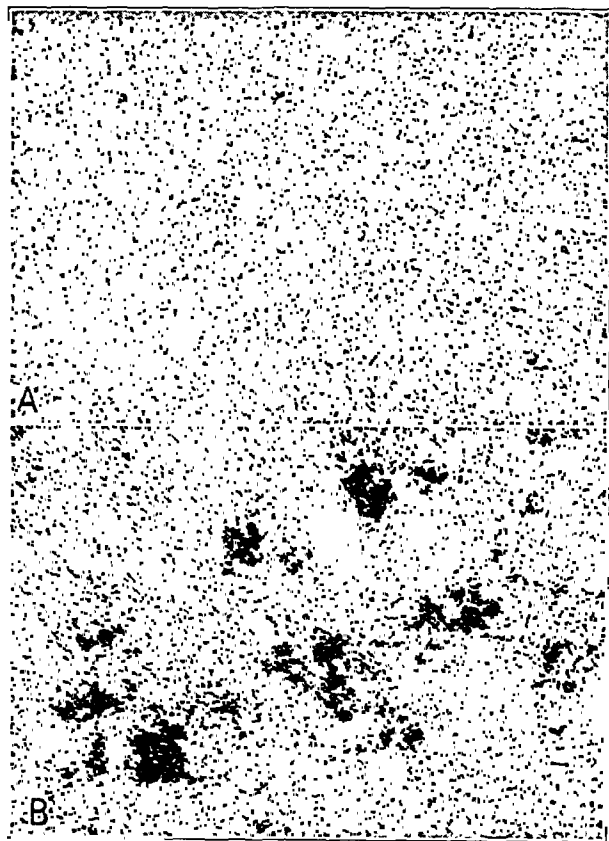

Fig. 2.—Low power photomicrographs of compatibility tests showing (A) compatibility and (B) incompatibility (2:10 mixtures of 50 per cent whole blood suspensions at the end of fifteen minutes).

agglutination power as determined by slide titration of agglutinins.¹⁴ These serums excelled the requirements of Coca's grade I for commercial test serums,¹⁵ as shown in the accompanying table, without any artificial concentration such as the alternate freezing and thawing proposed by Terry.¹⁵

For many years we had used home-made or commercial serums of indifferent quality, relying on cross-matching for safety, and employed a modification of Minot's method for grouping. Blood was obtained by venipuncture and three drops was mixed with a test tube full of saline solution to make an uncitrated cell suspension. The remainder was allowed to clot and was then centrifugated to separate the serum. Agglutination was determined microscopically in petrolatum-

rimmed cover slip preparations of cell suspension mixed with test serum and allowed to stand for from twenty to thirty minutes. For direct matching we had always used Moss's method¹⁶ simplified by elimination of citrating and washing of the cells. Reciprocal hanging drop preparations of equal parts of serum and saline cell suspension were observed microscopically after mechanical shaking for from thirty to sixty minutes.

In order to prove the greater efficiency and reliability claimed for the combined Vincent and Coca procedures, all groupings and matchings for transfusions given in the surgical service during a period of two months were determined both by the older methods and by our new Vincent-Coca technic. These examinations were made in parallel series on more than 200 consecutive specimens of blood. In each instance the new technic was tried first and then checked by the older methods. Not only was each pair of readings in agreement but in every instance the criteria of agglutination were more promptly and clearly defined with the Vincent-Coca procedure. The group could be determined by the open macroscopic method in a total elapsed time of from two or three minutes, and the interval of fifteen minutes prescribed for observation of the compatibility test proved more than ample, as in no case did agglutination appear after five minutes that had not already occurred. "Universal" donors with agglutinin titer potentially dangerous for A or B recipients could be detected by agglutination in the 1:5 mixture of donor's and recipient's blood, and many times we were able to employ emergency "universal" donors with perfect safety. Occasionally "universal" donors were used two or three times for one patient without ill effect. By virtue of the same quantitative feature, low titered A donors and occasionally B donors were safely selected for "universal" recipients.¹¹ On completion of these studies we abandoned the old modified Moss and Minot methods and adopted the combined Vincent-Coca technic as a routine. Over a period of nine months blood has been grouped and matched by this method for more than 400 consecutive transfusions without a single reaction due to incompatibility.

SUMMARY AND CONCLUSIONS

This technic combines the principles of the Vincent open macroscopic method for blood grouping and the Coca compatibility test for direct matching.

The advantages of these methods in general, and the combined technic in particular, may be summarized as follows:

1. Both grouping and compatibility may be determined with approximately ten drops of defibrinated whole blood obtained by finger puncture.

2. Venipuncture and separation of cells and serum are unnecessary. This is particularly advantageous when donors must be selected in emergencies from large groups of unknown volunteers, as it saves the time required for preparation of needles and syringes, suspensions and serum.

3. The veins of patients requiring repeated intravenous therapy may be conserved.

4. Provided standardized, high titered test serums are employed, the blood group is usually obvious in less than one minute.

5. Compatibility may be determined with a wide margin of safety in fifteen minutes, and the conditions and

proportions of the proposed transfusion may be duplicated beforehand in vitro, both qualitatively and quantitatively.

6. The time and material consumed in making cover slip preparations are saved.

7. "Universal" donors with agglutinin titer dangerous for A or B recipients can be detected by the 1:5 mixture of donor's and recipient's blood.

8. Low titered A donors may be selected for "universal" recipients.

9. The total elapsed time from the arrival of unknown donors to the final reading of the compatibility test has been reduced to thirty minutes, and often the blood may be drawn in twenty minutes pending the final reading.

SWELLING OF THE ARM FOLLOWING RADICAL MAMMECTOMY

RÔLE OF THE AXILLARY VEIN IN PRODUCTION OF EDEMA OF THE ARM FOLLOWING RADICAL REMOVAL OF THE BREAST

JAMES ROSS VEAL, M.D.

NEW ORLEANS

The swelling of the arm which may follow radical mamnectomy for cancer of the breast is still a problem that occasionally confronts every surgeon who performs this operation, though for some reason the literature is singularly barren of any recent discussion of it. The classic contribution to the subject was made by Halsted¹ in 1921, in a paper entitled "The Swelling of the Arm After Operation for Cancer of the Breast—Elephantiasis Chirurgical: Its Causes and Prevention," and reference to this study is necessarily the starting point of any new consideration of this problem. Indeed, nothing of any special importance has been added to the subject since the publication of that paper.

As Halsted¹ points out, his original operation for cancer of the breast, which "lies buried," as he puts it, in a paper under another title published in 1891, was practically the only procedure used in his clinic until 1913. Excellent as the operation was in its general principles, it had many disadvantages, one of the chief of which was the marked narrowing of the axillary fossa caused by the method employed in the radical dissection of the axilla, as a result of which there was frequently a marked limitation of the movement of the arm. In 1913, therefore, he devised another method of radical mamnectomy, and that new procedure had been in use nine years when the 1921 paper appeared. His comment on it can best be quoted in his own words:

"Nine years have now elapsed," he writes, "since the publication of my paper on 'Developments in the Skin-Grafting Operation for Cancer of the Breast,' in which a modified incision and radical changes in the manner of closing the wound were advocated; but I was not then able to offer an explanation altogether satisfactory to myself of the fact that the swelling of the arm which not infrequently followed our original procedure became almost immediately after the adoption of the modifications described in the latter paper a complication of rare occurrence." In other words, as not infrequently happens, a procedure devised to remedy one

condition accidentally produced excellent results in another toward which it was not primarily directed.

Rare though the complication had become, however, it was still occurring, and Halsted had devoted much thought and effort toward its elucidation. Experimental attempts to produce edema of the extremities by the mere severing of lymphatics and veins had not been successful. In these experiments, performed by Reichert and Bidgood in Halsted's own laboratory, all the tissues of the thigh were severed except the femoral artery and vein, the main nerve trunks and the bone. The severed structures were then very carefully reunited by suture. Seven or eight days later, after the reactionary swelling inevitable in such a procedure had subsided, the femoral vein, the only venous structure not previously divided, was ligated below the line of suture. No demonstrable change occurred in the size of the limb, and it was clearly evident that within the brief time which had elapsed since the first operation the lymphaticovenous circulation had been reestablished through the line of suture and the scar. Yet in man a similar occlusion of the axillary vein would produce edema of the hand and arm. That is amply demonstrated by cases in which venous ligation must be done, as in some cases of radical amputation of the breast or in cases of primary or effort thrombosis.

From the negative results of this experimental study and on the basis of his clinical observations, Halsted concluded that the chief cause of late postoperative swelling of the arm after radical mastectomy was a recurrent streptococcal infection of the lymphatics, which he named surgical elephantiasis, or elephantiasis chirurgica. Obstruction of the axillary vein might play some part, he granted, but he did not believe that occlusion of either the venous or the lymphatic channels was sufficient to bring about such a result. His own theory was that infection must necessarily be added to the occlusion. This infection, he believed, usually occurred at operation, though it might not become evident until months or years later, or it might be a reactive inflammation incident to a rapidly growing neoplasm and arising from carcinoma of the axillary glands. Whatever the cause, the result was the same: a brawny, persistent edema of the hand and arm, associated with recurrent attacks of low grade inflammation of the lymphatics and accompanied by systemic reactions such as malaise, low grade fever, and even chills.

Halsted's explanation has been more or less widely accepted to explain postoperative edema of the arm ever since he advanced it, but it obviously does not fit all cases. Not all postoperative edema meets his description, and in very many cases the clinical picture he outlines is entirely lacking. The natural presumption, therefore, is that the axillary vein must play some more important rôle in the production of postoperative edema of the arm than Halsted was willing to assign to it. With the recent development of vasography, consequent on introduction of opaque mediums for visualization of the vascular tree, it has been possible to clear up this point, and I am reporting twenty cases of postoperative edema of the arm which I have studied by this method.

By means of the introduction of stabilized thorium dioxide into the median basilic, the basilic or the

brachial vein I have found it possible to visualize the entire brachial, axillary and subclavian venous system, as well as their collateral veins.² As a result, I have been able to demonstrate points of constriction or occlusion in the axillary vein and to say with a fair degree of positiveness that this vein does or does not play a part in the production of the postoperative edema in any given case. The technic I shall discuss later, but I might say at this point that the agent which I have employed for this purpose is stabilized thorium dioxide. I have used this substance in more than 400 cases of vascular disease during the last four years. I have employed it in doses ranging from 5 to 20 cc., depending on the vessels to be visualized, and with the proper technic have found it entirely satisfactory and free from bad results of any sort. It does not cause pain, it does not damage the blood vessels, and I have seen no immediate or permanent ill effects follow its employment.

Fig. 1.—Patient showing persistent, brawny edema and recurrent carcinoma of the breast. She also gave a history of recurrent redness and tenderness of the entire arm. Note absence of constriction of axillary vein in either abducted or adducted position.

On the basis of my own study, combined with the physical observations and clinical course in the small group of cases that I have observed, I have devised a triple classification for postoperative edema of the arm: lymphatic obstruction (the elephantiasis chirurgica of Halsted), axillary vein constriction or occlusion, and combined lymphatic and venous obstruction. The basis of this classification I shall set forth in the discussion of each group.

LYMPHATIC OBSTRUCTION

The lymphatic type of obstruction may appear shortly after operation or may become apparent months or even years later. The edema is of the type always associated with lymphatic obstruction. It is persistent and brawny, it is only slightly affected by rest, massage or elevation, and it may be associated, as Halsted noted, with recurrent inflammatory reactions. The pathology is essentially a lymphatic obstruction caused by lymphangitis.

2. Veal, J. R., and McFetridge, E. M.: Primary Axillary Thrombosis: Anatomic and Roentgenologic Study of Certain Etiologic Factors, and a Consideration of Venography as a Diagnostic Measure, *Arch. Surg.* 51: 271-289 (Aug.) 1935

which, as Halsted pointed out, is apparently of streptococcic origin. My study of the local vascular supply after its visualization by thorium dioxide confirms, at least by inference, the lymphatic origin of this type of edema; the axillary vein shows no constriction or obstruction at any point throughout its course (fig. 1), and while I cannot say positively, since the tributaries are not visualized, that they play no part in the production of the edema, the inference is that they do not. Certainly the venous supply seems entirely adequate.

VENOUS OBSTRUCTION

In the group of cases that I have classified as due to venous obstruction the clinical picture is very different. In them the edema is soft and pitting in type, and it subsides partially or completely when the arm is elevated. The many cases in which this type of edema is

with the cervical veins. My studies show that when the vein is only partially occluded there is little evidence of collateral circulation, whereas a more or less adequate collateral circulation always tends to develop if the vein is completely occluded.

In the cases that I have studied, various causes of obstruction of the axillary vein are evident. Frequently the point of constriction is at the site of scar formation from the axillary dissection and operative incision (fig. 4). As one of the cases demonstrates, such scars may contract and actually include the axillary vein in the fibrous tissue. Another case of complete occlusion resulted from the attachment of the scar at the apex of the axilla. I have concluded, too, that operative trauma undoubtedly plays an important part in such occlusions. The vein may be accidentally torn and require ligation, or a thrombosis may develop as the

result of the careless placing of hemostats. In still other cases, constriction or thrombosis may be caused by the ligation of the tributaries too close to the parent vein. A large fat fold, again, may develop in the axillary region, impinging on the vein and producing obstruction (fig. 6).

An important cause of constriction or obstruction of the axillary vein is the pressure of enlarged lymph nodes from recurrent carcinoma. It should be pointed out, too, that the original malignant growth may invade the vein and cause a preoperative edema of the arm. Such a case in my own series is worth reporting in detail:

A Negro woman, aged 56, noted a mass in her left breast six months before she applied for treatment. Two months later the left arm became enlarged and swollen, the swelling lasting for some six weeks. When she was examined after her admission to the hospital there was no evidence of swelling in the arm, and the carcinoma was moderately advanced. Vasography showed

complete occlusion of the axillary vein, with five smaller collateral veins encircling the cancerous axillary nodes palpable in the axilla (fig. 2). Clearly the obstruction to the axillary vein was adequately cared for by the development of this collateral circulation. At operation the axillary vein presented itself merely as a hard cord. Unfortunately, in order to clean out the axilla, it was necessary to sacrifice several collateral vessels, and the edema that developed promptly after operation was not unexpected. At this time, four months after operation, the arm is still swollen.

Practically no attention has been paid, so far as I can determine, to the position of the arm in the production of the edema, yet my own observation shows that this is a very important consideration. Sometimes careful questioning was necessary to produce the information, but several patients observed for themselves that edema

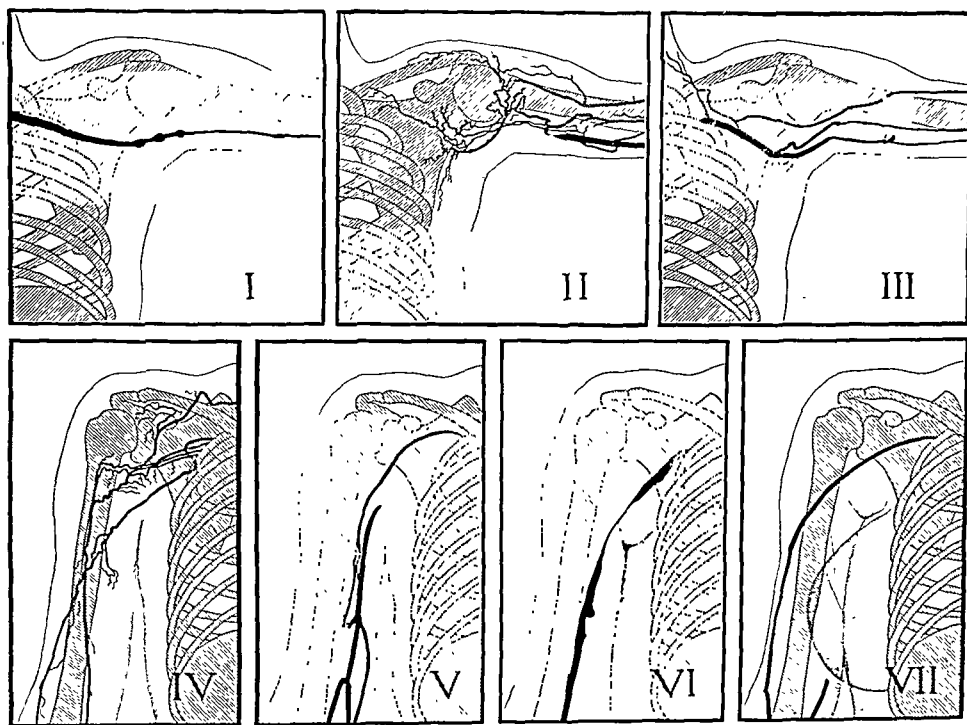

Fig. 2.—Types of axillary vein obstruction in a series of cases of edema of the arm following radical removal of the breast. Pen drawings from venographs. I. Normal axillary vein. Note position of valves and general contour of vein. II. Complete axillary vein obstruction with development of collateral circulation. III. Complete occlusion of the axillary vein from scar formation. Note the development of collaterals and the backflow of opaque mediums into the tributaries. IV. Complete axillary vein occlusion from invasion by carcinoma. Note development of collaterals. Edema subsided in this arm after the development of these collaterals. V. Axillary vein constriction with arm in dependent position. The constriction occurred at the site of recurrence of the carcinoma. The vein is patent when the arm is abducted. VI. Constriction of axillary vein by fat fold. Edema only when arm is dependent. Edema rapidly subsides when arm is elevated. Axillary vein is patent when arm is abducted. VII. Complete occlusion of axillary and brachial veins by pressure of large fat folds when arm is held against the side. Edema occurs only when arm is dependent, and subsides rapidly when arm is held away from side.

apparent clearly offer the chief obstacle to a wholesale acceptance of Halsted's theory of recurrent streptococcic lymphangitis as the explanation of all cases in which this complication is apparent.

Vasography in this type of case clearly demonstrates the vascular origin of the edema. The axillary vein is shown to be obstructed or constricted at one point or more than one point along its course (fig. 2). If an adequate collateral circulation has developed, a fact that is evidenced clinically by improvement in the edema or its complete disappearance, new venous channels are seen in the axillary region, or enlarged and tortuous veins may be present in the shoulder and upper part of the chest (fig. 3); such veins may unite with the external mammary vein or may extend upward and unite

did not develop when the arm was held away from the side but only when it hung for a considerable period of time in walking or standing; one patient habitually carried a purse under her arm to preserve the abducted position and thus prevent the edema.

With this point in mind I took all the pictures in two positions, one with the arm by the side, the other with it abducted to an angle of from 45 to 60 degrees, depending on the freedom of movement the axillary scar permitted the patient. In the cases in which edema developed only when the arm was dependent, I noted a uniform constriction of the axillary vein in the first picture and a uniform absence of constriction in the picture taken with the arm in abduction (fig. 7). Failure to take into consideration the position of the arm has undoubtedly led to many errors in the interpretation

Fig. 3.—Complete obstruction of axillary vein from recurrent carcinoma. Note marked development of collaterals over shoulder and chest. Infra-red photograph.

of the rôle of the axillary vein in the production of postoperative edema. At operation or autopsy the vein may seem to be patent merely because examination is made only in the position of abduction.

LYMPHATICOVENOUS OBSTRUCTION

It is a well known fact that prolonged swelling arising from venous constriction or occlusion is likely, if unrelieved, to involve the lymphatic channels also, so that the pathologic condition presented is eventually a dual one. In this type of case the edema is soft and pitting at the onset, to become finally the persistent, brawny type described by Halsted. In such cases there is little or no improvement in the edema after postural treatment or rest and, while attacks of recurrent lymphangitis may occur, they are not usual. In other words, we are dealing in this group of cases with a primary swelling due to venous obstruction, on which is superimposed lymphatic obstruction. The diagnosis is made on the evidence of constriction or obstruction, as shown by vasography, plus the clinical evidence of the lymphatic type of edema.

The technic of vasography is simple. The picture is taken on a 14 by 17 plate, enclosed in a cassette, which is placed beneath the axillary region as the patient lies prone on the x-ray table. The injection is begun only

Fig. 4.—Obstruction of axillary vein by contraction of scar in axilla. The scar tissue has incarcerated the axillary vein. Note development of collaterals as shown by infra-red photograph.

after the machine is focused and all preparations have been made to take the picture; this point is essential. Not more than 12 cc. of thorium dioxide is used; it is

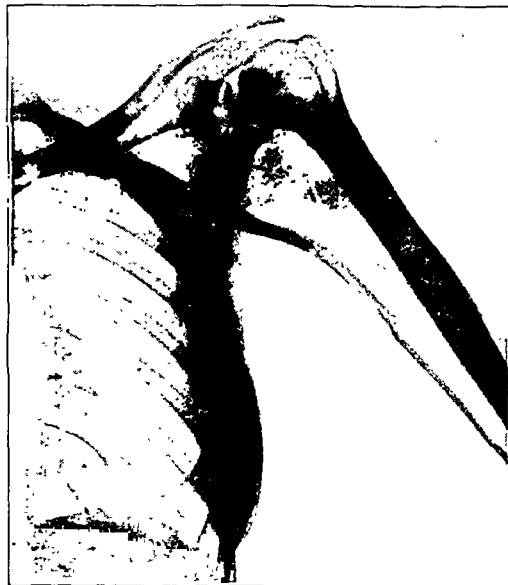

Fig. 5.—Normal axillary vein

placed in a 20 cc. syringe, to which a 20 gage needle is attached. Five or 6 cc. of the solution is injected into the vein selected for puncture, the injection being made slowly and taking at least eight to ten seconds. Immediately on its conclusion, without removal of the needle,

the first exposure is made, the arm being held at an angle of from 45 to 60 degrees away from the chest. Then the arm is brought down to its usual dependent position by the side, a fresh plate is inserted in the cassette, and the remaining solution is injected. The second exposure is made immediately on its completion.

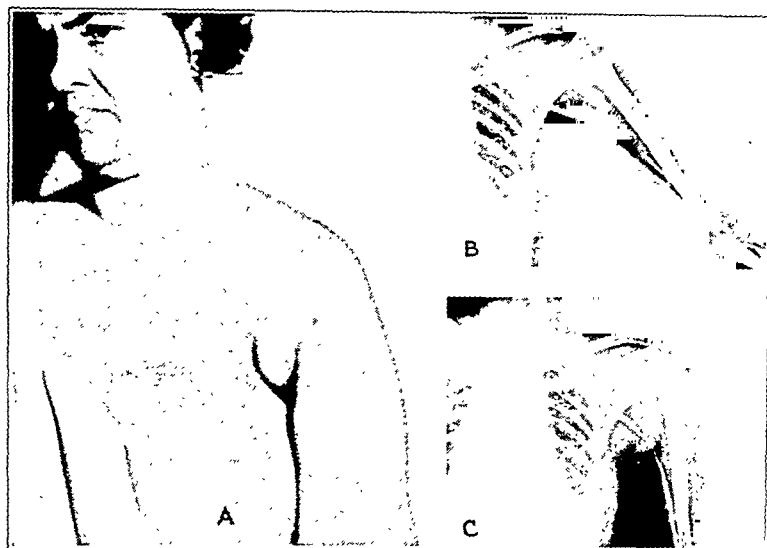

Fig. 6.—The patient presented soft, pitting edema of the arm only when the arm was dependent. Axillary vein patent throughout with arm abducted. On lowering the arm to the side there was marked constriction of the axillary vein by impingement on it of the large fat fold seen in the photograph.

The median antecubital vein may be used as a point of injection, but I have found that the results are not nearly so good as when the brachial or basilic vein is used. The reason is obvious, that the small amount of solution used may flow into the cephalic vein when it reaches the bifurcation of the median antecubital vein, instead of into the axillary vein. When the basilic or the brachial vein is used, the brachial, the axillary and the subclavian veins are visualized to a point near the junction with the innominate vein. It is not possible, with so small an amount of solution, to visualize any of the larger vessels entering the heart. If the arm is so badly swollen that the vein to be injected cannot be identified, a rest of several days, with postural treatment, may improve the condition. If it does not, the brachial artery can be palpated just above the antecubital space and the needle inserted into the brachial vein just to the side of it. I have not found it necessary in any case to make an open incision to expose the vein.

The normal axillary vein is uniform in outline and often has several valves near its middle portion (fig. 5). There is no point of constriction or obstruction, no tributaries are visualized, and there is no evidence of a collateral circulation. The vein gradually enlarges as it approaches the subclavian vein, which itself is visualized for 3 or 4 cm. The innominate vein is not visualized. In the abnormal cases the points of constriction or partial or complete obstruction are readily evident and need no special discussion (fig. 2). As I have already pointed out, there is little or no evidence of collateral circulation when the obstruction is incomplete, but usually definite evidence when it is complete.

While this paper is not a therapeutic consideration of edema of the arm, it might be well to mention several points that naturally present themselves in the light of the previous discussion. Radical removal of the breast is a mutilating operation under the best of circumstances and, like all mutilating procedures, it carries its own penalties. Regardless of the type of incision, and even when the utmost care is exercised, the necessary dissection results in more or less axillary scarring and the loss of more or less elasticity of the overlying skin. Under the happiest circumstances the axillary fossa becomes shallower and narrower, and the removal of the muscular portion of the anterior axillary fold is an essential part of the procedure. It is scarcely necessary to labor the point that all these changes will be exaggerated when incisions are unwisely extended into the axilla or when the axillary dissection is carelessly done.

Since the axillary vein, as I have pointed out, may be included in the axillary scar (fig. 4), the skin in this area should be kept as free from scarring as possible. In thin subjects it may be wise to transplant a small amount of fat tissue between the axillary vein and the skin, in order to avoid this contingency. Stout patients, on the other hand, should be warned not to gain weight following operation, for equally bad results may follow the impingement of a fold of fat on the axillary vein. The vein itself should be handled very gently and under no circumstances should drains be laid against it. The flow of blood in the axillary vein, in the recumbent position with the arm by the side, is slow. I have demonstrated this point in studying by vasography the effects of position on the rate of

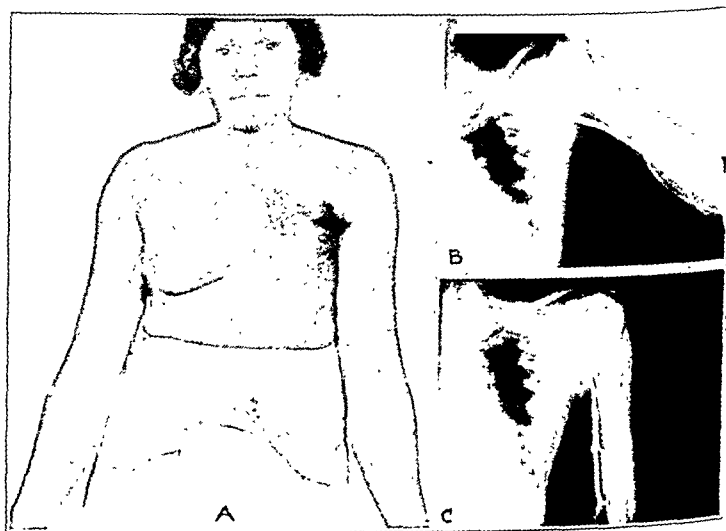

Fig. 7.—Recurrent carcinoma in scar and axilla. Soft, pitting edema when arm is dependent rapidly subsides when arm is elevated. Note patency of axillary vein when arm is abducted and constriction when arm hangs by the side. The point of constriction is the site of recurrent carcinoma.

blood flow in the axillary vein. Trauma to the vein, therefore, may easily produce a thrombosis, as may the placing of ligatures on the tributary veins too close to the parent vein. The cephalic vein should not be sacrificed, for it plays an essential part in the venous return. It is easier to prevent postoperative edema of the arm after radical mastectomy than to cure it when

it has occurred. Indeed, no satisfactory procedure for its relief has yet been devised, and when the underlying cause is a recurrence of the malignant condition in the incision or in the axilla, the situation is frankly hopeless.

SUMMARY

1. Edema of the arm following radical removal of the breast may be due to lymphatic obstruction, to venous obstruction, or to a combination of the two factors. The present small series of twenty cases indicates that venous obstruction is the most common cause.

2. Obstruction of the axillary vein is due to various causes, the chief of which are the pressure of the malignant growth itself in its primary or secondary manifestations, scar formation, and the impingement of fat folds.

3. Constriction may occur only when the arm is dependent and may disappear when the elevation of the arm restores the patency of the vein.

4. A collateral circulation may develop adequate to take care of the venous return.

5. Venography with stabilized thorium dioxide is of value in determining the cause of the edema, but no procedures have yet been devised to remedy it. The wisdom of prophylaxis is therefore obvious.

SIGNIFICANCE OF GONOCOCCUS COMPLEMENT FIXATION TEST AS A DIAGNOSTIC AID

IN THE STUDY OF ARTHRITIS

CHARLES F. WARREN, M.D.

BROOKLYN

WILLIAM A. HINTON, M.D.

AND

WALTER BAUER, M.D.

BOSTON

The prognosis in any case of gonorrheal arthritis is dependent on (1) the virulence of the offending gonococcus strain, (2) the persistence of the local infection, (3) the resistance of the individual and (4) the promptness with which appropriate treatment is instituted. However, the prompt institution of appropriate treatment is dependent on one's ability to distinguish gonorrheal arthritis from the other arthritides. Such differentiation is at times difficult because one can neither elicit a history of previous gonorrheal infection nor isolate the gonococcus from the focus of infection. In such instances the need of a laboratory test indicating the possible existence of a gonococcal infection is all too apparent.

Is the complement fixation test for the gonococcus as it is now done as a routine in public health laboratories sufficiently accurate to warrant its employment as a diagnostic aid in the study of arthritic patients? In order to answer this question one must do routine fixation tests on a large series of patients representing proved cases of the various arthritides, gonorrheal and nongonorrheal in origin. This we have done.

Dr. Warren was Dalton Scholar, Massachusetts General Hospital, 1933-1934 and 1934-1935.

The expenses of this investigation were defrayed in part by a grant from the Rockefeller Foundation.

This is publication 20 of the Robert W. Lovett Memorial for the study of crippling disease, Harvard Medical School.

From the Medical Clinic of the Massachusetts General Hospital, the Department of Medicine, Harvard Medical School, and the Wassermann Laboratory of the Department of Public Health of the Commonwealth of Massachusetts.

The reports of certain workers¹ would signify that it can be relied on as a diagnostic test, yet one finds few clinics in which it is employed with any regularity. Why it has never gained wide acceptance as a diagnostic aid in the study of patients with arthritis is not apparent. It may be that most physicians consider an additional laboratory test of this sort unnecessary. Such has not been our experience. We frequently have difficulty in establishing the diagnosis of gonorrheal arthritis because (1) it may come on months after the initial infection and (2) its clinical manifestations are frequently so varied that it mimics other types of arthritis. In consequence, many cases are misdiagnosed acute rheumatic fever, gout, nonspecific infectious arthritis, rheumatoid arthritis and the like. Others may have considered the reported series too small to consider that the results obtained were necessarily of significance or that the cases studied were not necessarily proved cases of gonorrheal arthritis. Negative fixation tests in proved cases of gonorrheal arthritis and false positive tests in nongonorrheal arthritic patients may have been another reason for not employing it regularly. Certainly our first experiences with the gonococcus complement fixation test in cases that were ultimately proved to be gonorrheal arthritis were sufficiently contradictory to discourage one from employing it as a routine diagnostic aid.

The two brief cases reported here illustrate how a positive fixation test may be the first clue that one is dealing with a case of gonorrheal arthritis and that a negative fixation test may be misleading if one fails to heed the suggested leads obtained in the history.

CASE 1.—Miss F. H. K., aged 19, was admitted to the medical ward Dec. 7, 1931, with a diagnosis of rheumatic fever. Nineteen days prior to entrance she contracted a mild infection of the upper respiratory tract. Three days later she considered herself well. Five days prior to entry her left knee became painful but showed no evidence of inflammation. That night she experienced chilly sensations and a true chill. For the next four days she suffered from a migratory arthritis involving the wrists, shoulders, elbows, fingers, knees, ankles and neck. Each joint was exquisitely painful to touch during the time of involvement but apparently normal when symptom free. She stated that she had never had a gonorrheal infection.

On entrance her temperature was 103 F. Leukocytes numbered 16,000, with 78 per cent polymorphonuclears. Physical examination was essentially negative except for moderate obesity and frontal sinus tenderness, and the wrists and the left knee were slightly swollen, red and tender. The cervical spine, temporomandibular joints, shoulders, elbows, wrists, fingers, knees and ankles were exquisitely tender on motion.

Because of the preceding infection of the upper respiratory tract, migratory arthritis and a drop in temperature following the administration of salicylates, a diagnosis of rheumatic fever was made. However, when she was seen four days after admission it was found that despite adequate doses of salicylates she continued to have a temperature of from 100 to 101 F. and required opiates to control the pain. At this time the only joints complained of were the wrists, fingers and left knee. The wrists, midphalangeal joints and left knee were red, hot, exquisitely tender to touch and painful on attempted motion. Because of the frank chill (period of metastasis) followed by a migratory arthritis sufficiently painful to require opiates, finally settling and remaining in a few joints, a diagnosis of gonorrheal arthritis was suggested, and a complement fixation test for the gonococcus, pelvic examination and complete set of pelvic smears were advised. The gynecologist reported the pelvic examination negative. Two complete sets of pelvic smears were negative for gonococci. Despite the suggested evidence of gonorrheal arthritis, a diagnosis of rheumatic fever was adhered to by some and agreed to by an orthopedic consultant.

December 15 her condition was essentially unchanged. The wrists and midphalangeal joints were subsiding but the left knee appeared more swollen, was hot to the touch and extremely painful and contained an increased amount of synovial fluid. On this day the complement fixation test was reported positive. Aspiration of the knee joint was advised.

In view of the orthopedic opinion, it was delayed. When it was done some fourteen days later a greenish purulent fluid was obtained. Stained smears of this fluid revealed gram-negative intracellular diplococci.

In this instance of an arthritis simulating rheumatic fever, the positive complement fixation test was the first clue that the suggested diagnosis of gonorrheal arthritis was correct. This first clue was finally confirmed by isolating the gonococcus on direct smear of the synovial fluid.

CASE 2.—Mrs. M. C., aged 34, entered the hospital Jan. 15, 1932, complaining of painful joints. Eleven weeks prior to entry she experienced a sudden onset of intermittent pain under the right costal margin without associated gastro-intestinal symptoms, jaundice or fever. The pain was so severe that she was given opiates. Forty-eight hours later she noted swelling and pain in the right shoulder sufficiently severe to limit all motions and to require opiates. The intense pain persisted for four weeks. She then noted swelling and pain of the second right toe. In addition, she had recurrent pain and stiffness in the left shoulder, cervical spine and right sternoclavicular joint. She admitted having dysuria during the first week of her illness.

Physical examination was essentially negative except for the skeletal system, which revealed 25 per cent limitation of all motions of the cervical spine, approximately 50 per cent limitation of all motions of the right shoulder and a red, indolent appearing, right second toe, which was tender on pressure or on extremes of motion. She was afebrile and did not have a leukocytosis or elevation of polymorphonuclear cells. Pelvic examination was negative except for a slight vaginal discharge.

Three complete sets of pelvic smears were negative for gonococci. The complement fixation test for the gonococcus was negative.

She had been married six months prior to her illness. Her husband admitted having had a gonorrheal infection three years before, with recurrent morning urethral discharge prior to his wife's illness. Therefore there was sufficient evidence to lead one to suspect that the existing arthritis was due to the gonococcus, but all efforts to prove this had been fruitless. She was finally given 50,000,000 gonococci subcutaneously in the form of a stock vaccine. Some thirty-six hours later there was noted an increase in the joint symptoms as well as the appearance of a red, painful, tender sternoclavicular joint. Forty-eight hours later she reported an increase in the vaginal discharge. Examination of vaginal smears taken at this time revealed intracellular gonococci.

In this case of suspected gonorrheal arthritis the complement fixation test was negative, yet the suspicion that the arthritis was gonorrheal in origin was sufficiently great to force one to continue the search for gonococci despite the negative fixation test. This case illustrates the necessity in certain instances of following leads obtained in the history despite the existence of a negative complement fixation test. It further illustrates that occasionally the administration of a gonococcus vaccine may be responsible for sufficient activation of the original focus to allow for the demonstration of the gonococcus.

Because of such discrepancies we undertook the study of a sufficiently large number of cases, representing the various types of joint disease, in order to establish the significance of the test as a diagnostic aid. We have employed the test with some regularity in the study of arthritic patients since 1931. During the next four years, 614 tests were done on serums from 316 patients. The analysis of this series of tests serves as the basis of this report.

I. THE GONOCOCCUS COMPLEMENT FIXATION TEST EMPLOYED

All tests were done in the Wassermann Laboratory of the Department of Public Health of the Commonwealth of Massachusetts. This test is done as follows:

The following reagents are used:

1. *Antigen*.—Four Torrey strains (numbers 8, 15, 32 and 34) of the gonococcus are grown on neutral veal, 1 per cent starch agar, for from twenty-four to forty-eight hours. This growth is washed off with 0.5 per cent phenol in distilled water and diluted according to the Hopkin method so that 2,500 million organisms are contained in 1 cc. This suspension is shaken in a shaking machine for about sixteen hours. It is then kept in a refrigerator.

2. *Complement*.—A 10 per cent solution of guinea-pig serum prepared from the mixed blood of five or more guinea-pigs.

3. *Sheep's Cells*.—A 5 per cent suspension of washed sheep's corpuscles. This is based on whole defibrinated blood and not on packed cells.

4. *Amboceptor*.—Antisheep, diluted so that 0.25 cc. induces hemolysis of 0.5 cc. of the washed sheep's corpuscles in the presence of 0.5 cc. of the complement. Twice this amount, or 0.5 cc., is used in the titration and tests.

5. *Saline*.—An 0.85 per cent solution of sodium chloride in distilled water.

6. *Sensitized Cells*.—Equal parts of the 5 per cent sheep's cells and diluted amboceptor.

7. *Patient's Serum*.—Inactivated by heating at 55 C. for one-half hour.

For each day's work the following routine is carried out: complement titration (table 1); antigen titration (table 2), and the test (table 3).

The tubes are incubated at 37 C. for one-half hour and are then read. The tube in row 1 that contains the smallest amount of complement causing complete

hemolysis is chosen as the unit of complement. The 10 per cent solution is then diluted so that 0.5 cc. contains two units. This is called dilute complement. The tubes in row 2 are used as controls of the hemolytic system and hemolysis should not occur in any one tube.

Incubation is carried out for forty minutes at 37 C. in a water bath, and 1 cc. of sensitized cells is added to each tube. The tubes are incubated again for one hour and then read; 0.05 cc. less than the largest amount of antigen that permits complete hemolysis is used in the test. If, for example, the tubes that contain 0.1 cc. and 0.2 cc. of antigen show complete hemolysis and the one that has 0.3 cc. shows partial hemolysis, then 0.15 cc. of antigen would be used in the test. This will be designated in table 3 as 0.*x* cc.

Saline solution is added to each tube to make the volume 1 cc.

After the tubes are incubated for forty minutes at 37 C. in a water bath, 1 cc. of sensitized cells is added to each tube and then incubated for another hour. The results in tube 1 are given in table 4.

For a satisfactory test, tube 2 (the antigen control) and tube 3 (the serum control) should show complete hemolysis.

Essentially all the serums were tested as described with the exception of a few in the earlier cases of gonorrheal arthritis, which were selected from the hospital records to supplement the present series. All tests reported as doubtful were omitted because it was found that approximately the same percentage of such reactions occurred in each type of arthritis studied.

II. THE CLASSIFICATION OF JOINT DISEASES

The patients in this series suffering from joint disease were classified according to a simple working plan. The use of some such classification is essential to the differentiation of the various arthritides. It has been our belief that a classification based on etiology best serves the practicing physician in diagnosing and treating patients with arthritis.

The classification we employ is as follows:

- A. *Joint Disease of Known Etiology*.—1. Traumatic; e. g., associated with internal derangement, and fractures into joints and so on.
2. Infection; e. g., due to the gonococcus, tubercle bacillus, streptococcus and other organisms.
3. Neuropathic; e. g., associated with tabes, syringomyelia, leprosy.
4. Metabolic; e. g., associated with gout.
5. Constitutional; e. g., arthritis associated with hemophilia.
6. Anaphylactic; e. g., arthritis associated with serum sickness.
- B. *Joint Disease of Unknown Etiology*.—1. Degenerative joint disease, degenerative, hypertrophic or osteo-arthritis.
2. Rheumatoid arthritis, proliferative, atrophic or chronic infectious arthritis.
- (a) Typical.
- (b) Atypical (often called nonspecific infectious arthritis because the causative bacteriologic agent cannot be demonstrated).
- (c) Spondylitis deformans, Strümpell-Marie or von Bechterew's type, or rheumatoid arthritis of the spine.
3. Rheumatic fever.

This classification is probably self explanatory save for the subdivisions under rheumatoid arthritis. Cases classified as typical rheumatoid arthritis probably require no further comment. However, the cases included in this series under the grouping atypical rheumatoid arthritis do. This group represents cases that do not exhibit the characteristic history, habitus and physical conditions observed in a typical case of rheumatoid arthritis. The onset is usually sudden,

without preceding prodromes, often following an acute infection or associated with some obvious focus of infection. Such patients do not present the usual asthenic type of habitus with evidence of increased vasomotor activity. The joint involvement is not symmetrical, and the large joints are more commonly affected. The monarticular form may be encountered. The arthritis is frequently polyarticular and migratory in nature. The response to salicylates occasionally may be complete. Such patients may recover completely even though the supposed causative focus of infection is not removed. Such remissions or periods of complete recovery may last for months or years but will subsequently be followed by a relapse. The disease in such instances may be characterized by a number of remissions and relapses before going into the chronic progressive phase.

The fact that the remissions frequently occur spontaneously has caused many workers to draw erroneous conclusions concerning the specific cause and cure of this, the atypical form of rheumatoid arthritis. They are all too frequently labeled the "focal infection type of arthritis" or the nonspecific infectious type of

TABLE 3.—The Test

	Tube 1	Tube 2	Tube 3
Patient's serum	0.1 cc.	0.2 cc.
Antigen	0. <i>x</i> cc.	0. <i>x</i> cc.	
Dilute complement	0.5 cc.	0.5 cc.	0.5 cc.

TABLE 4.—Results in Tube 1

5 equals complete inhibition of hemolysis
4 equals 70 to 90% inhibition of hemolysis
3 equals 50 to 70% inhibition of hemolysis
2 equals 20 to 50% inhibition of hemolysis
1 equals up to 20% inhibition of hemolysis
Reactions are reported as:
Positive, from 50 to 100% inhibition of hemolysis
Doubtful, from 20 to 50% inhibition of hemolysis
Negative, up to 20% inhibition of hemolysis

arthritis. If, in such cases, one will allow for the passage of time before making an absolute diagnosis, the true nature of the type of arthritis present will usually become all too apparent.

We well appreciate that, if such a disease as non-specific infectious arthritis (cases in which the exact offending bacteriologic agent is never identified) occurs, a few of our atypical rheumatoid arthritic cases should have been so classified. However, in view of the subsequent events in this group of patients we believe that the original diagnosis was justified. Irrespective of our interpretation of this group, it is essential to separate them, because they usually carry a better immediate prognosis. In this particular study some such subdivision is desired because such cases represent the type of arthritis that might readily be confused with gonorrheal arthritis.

Because spondylitis may be a resulting complication of a gonorrheal infection, the belief is held by some that spondylitis of the Strümpell-Marie type is due to the gonococcus.² It is true that it occurs more often in men, frequently in association with a prostatitis. However, if one follows a group of patients with spondylitis for a sufficiently long time, many are encountered in whom multiple joint involvement subsequently develops indistinguishable from rheumatoid arthritis. As a rule, the spondylitis appears first; however, one does see patients in whom the spondylitis developed

2. Miller, J. L.: Chronic Rheumatic Diseases of the Spine, Arch. Int. Med. 54: 161-169 (Aug.) 1934.

subsequent to multiple joint involvement. For these and other reasons we are of the belief that this group of arthritic cases comprises a subdivision of the rheumatoid type of arthritis.

III. METHODS EMPLOYED IN STUDYING EACH PATIENT

It is obvious that, if one is to evaluate correctly the significance of the gonococcus complement fixation test as a diagnostic aid in the study of patients with arthritis, one must be certain of two facts concerning all patients studied: (1) that the diagnosis as to the type of joint disease present is correct and (2) that the patient does or does not have a coexisting gonorrheal infection. Therefore, the following minimal studies were carried out on all patients: (1) a history taken by at least two physicians, (2) a complete physical examination, (3) roentgenograms of at least the involved joints, (4) a fasting blood uric acid, (5)

In three instances a diagnosis of rheumatoid arthritis with an accompanying gonorrheal infection was made. These three cases will be found recorded separately.

RESULTS

An examination of table 5 shows that 91.3 per cent of the 439 tests done on the serums of 206 individuals with various types of joint diseases in whom no history or physical manifestations suggestive of gonorrheal infection could be found gave negative reactions at all times. Likewise, 100 per cent of all tests done on the serums of thirty-three patients suffering from maladies other than joint disease or in whom no organic disease was discovered were negative. On the other hand, serums from sixty-eight, or 91.9 per cent, of seventy-four patients diagnosed as having a proved or probable gonorrheal arthritis gave a positive reaction at some time during the course of their disease. If the results in this group of patients are studied in more

* Strümpell-Marie type.

a sedimentation rate, (6) a careful search for foci of infection by a nose and throat specialist, a gynecologist and a genito-urinary consultant, (7) at least one complete set of pelvic smears or smears obtained at the time of prostatic massage, and (8) at least one complement fixation test for the gonococcus. In any suggestive cases, certain of these tests were done repeatedly. The final diagnosis was often deferred until the course of the disease had been observed for one or more years. In this way many errors in diagnosis and classification of the arthritis were avoided and in turn errors in the interpretation of the value of the complement fixation test were prevented.

No case was included as proved gonorrheal arthritis unless the following requirements were met: (1) a history or physical abnormalities indicating a previous or existing gonorrheal infection, (2) a history of joint disease consistent with gonorrheal arthritis and (3) the isolation on smear or culture of the gonococcus from the primary focus or synovial fluid. Probable gonorrheal arthritis was diagnosed when the first two of these requirements were met, but no gonococci were ever isolated. The follow-up studies in these cases proved the original diagnosis to be correct.

detail, one finds that at least one positive fixation test was obtained in 100 per cent of the cases, provided the serum was obtained during the period of active arthritis. However, one notes that in only 80.7 per cent of the proved cases of gonorrheal arthritis and 63.6 per cent of the probable cases was the test always positive. One further observes that in six of the proved cases all tests done were always negative. Only one sample of serum was obtained from each of these six patients. In four instances the test was done on serums obtained early in the disease (first, second, fourth and sixth days respectively), and in the other two patients the test was done on serums obtained two and two and one-half years after all joint symptoms had disappeared.

The percentages just noted undoubtedly give too favorable an impression as to the value of the test as a diagnostic aid. The practical question to be answered is If the test is positive, what is the probability that the arthritic patient has a gonorrheal arthritis, and, if negative, how certain can one be that the gonococcus has been ruled out as the etiologic agent? One hundred and forty positive tests were obtained in ninety-one of the 316 patients. Of these, 108 tests were done on serums obtained from patients in whom the final diag-

nosis was either proved or probable gonorrheal arthritis (seventy-four cases) and rheumatoid arthritis with an accompanying gonorrhea (three cases). Thus, only 77 per cent of our routine clinic tests done during all phases of the disease that were reported as positive agreed with the final clinical diagnosis. Likewise, twenty-three of 125, or 18.4 per cent, tests made on patients with proved or probable gonorrheal arthritis were negative. Therefore, in tests taken as a routine in an arthritic clinic at all stages of the arthritic process a positive fixation pointed to the gonococcus as the etiologic agent of the arthritis in approximately 80 per cent of the cases, whereas a negative test failed to rule out the gonococcus as the etiologic agent in approximately one case in five.

The cases of typical rheumatoid arthritis represent the largest series of any one type of arthritis contained in our control group. As one can see from table 5, 352 tests were done on the serums of 151 such patients. The serums of three, or 1.9 per cent, of these patients were always positive. Thirteen cases, or 8.6 per cent, gave both positive and negative tests. However, 325 of the 352 tests were negative (92.3 per cent). From these results on 151 proved cases of rheumatoid arthritis it is apparent that the complement fixation test for the gonococcus can be relied on as a diagnostic aid.

A comparison of the results of the complement fixation test in gonorrheal arthritis with those in atypical rheumatoid arthritis and rheumatic fever is more pertinent because these arthritides are more apt to mimic gonorrheal arthritis. Only twelve tests were made on patients with acute rheumatic fever, but these were all negative. Of the twenty tests done on serums from fifteen patients with atypical rheumatoid arthritis, only one positive test was recorded. Such close agreement with the clinical diagnoses would seem to indicate that the fixation test would again serve as a diagnostic aid.

The cases of degenerative arthritis form an important part of the control series because the majority of such individuals are past the age when active gonorrhea is usually encountered. The tests in this series, nineteen tests on the serums of eleven patients, were all negative.

Because of the supposed frequent association of a specific or a nonspecific prostatitis with spondylitis deformans,² it is interesting to note that fourteen of fifteen tests made on these nine male patients were negative.³ In this small series, three patients gave a history of gonorrhea eight, ten and thirteen years previously, but in each instance the onset of the spondylitis antedated the genital infection from one to four years. Only one of these three men still had a prostatitis (from which no gonococci could be isolated) at the time of entry to the hospital. The one man in whom a positive test occurred gave no history or other definite evidence of gonorrhea. In two other cases a nonspecific prostatitis was found.

Fifteen of sixteen tests in eight cases of gout were likewise negative, the one positive test being obtained in a woman with no changes suggestive of gonorrhea.

As can be seen from table 5, one may obtain varying results in the same individual. In this series, thirty out of 316 patients gave both positive and negative results. For instance, tests made on the serums of a woman with undoubted rheumatoid arthritis and in

whom no evidence of gonorrhea was ever demonstrable ran as follows: + ? — ? — ? + ? ? — — —. Similarly a series of tests taken in a case of gonorrheal arthritis were reported as — + — +. Such results indicate that, unless the test as used in this series is improved on, one cannot rely on the test in any single case, unless the clinical course of the arthritis in question is carefully evaluated. Further evidence that the gonococcus complement fixation method employed in this particular study is anything but 100 per cent diagnostic is well illustrated by the following case:

CASE 3.—A man, aged 38, was recently seen in consultation at another hospital. He gave a history of undoubted gonorrheal genital infection with frequent exacerbations of the genito-urinary symptoms. These genito-urinary exacerbations were always accompanied by widespread arthritis. When he was seen in the seventh week of his illness, it was found that the prostatic smears contained undoubted gonococci. Yet fixation tests done at weekly intervals for the preceding seven weeks had all been negative. Possible reasons for these variations and a discussion of certain technical considerations will follow.

The diagnostic significance of the test is further limited because of the occurrence of false positive reactions in the absence of gonorrheal arthritis. If the clinical course of each patient is not taken into consideration, calculations reveal that, given three positive tests, only two were correct, the third being a false positive reaction. However, such calculations exaggerate the significance of the false positive reactions, because if the clinical course of the arthritis is taken into consideration most of them will be found to be of no significance and in consequence will be eliminated. If the number of gonorrheal arthritic cases and those of nongonorrheal origin resembling gonorrheal arthritis are about equal, only one out of every ten positive tests will be misleading.

It is far better that the diagnostic error should be in this direction, because specific treatment such as properly supervised generalized diathermy will probably not do the patient in question any harm, whereas undue delay in a case of gonorrheal arthritis may allow for serious, irreparable damage to take place before the institution of such therapy.

COMMENT

The first requisite to a correct evaluation of the gonococcus complement fixation test as a diagnostic aid in the study of arthritic patients is that the cases so studied should be correctly diagnosed. In the present series every effort was made to meet this requirement by complying with the requirements set forth under Methods Employed in Studying Each Patient. In certain instances the final diagnosis was deferred until the course of the disease had been observed for one or more years. If, after such study and observation, there was any question as to the final diagnosis, the case was omitted from this series. (Three such cases were omitted; the tests in all were negative.) Therefore it is our belief that few if any errors in the interpretation of the value of this test as a diagnostic aid can be ascribed to mistaken diagnoses.

It is apparent from our results that even when the first requisite is met the gonococcus complement fixation reaction is not as specific a diagnostic test as the Wassermann reaction. From our experience with the test as carried out in this study, it is apparent that the test is not sufficiently perfect to eliminate nonspecific reactions. It would also seem that antibodies demonstrable by complement fixation may not appear in the blood stream in all cases. However, the chief

3. Tests on five additional patients (three males and two females) were also negative. Two of these five patients admitted having had a previous gonorrheal infection but not one of them had any evidence of such at the time they were examined. In both cases the spondylitis antedated the gonorrheal infection.

technical imperfections of the method employed are due to (1) the relatively large amount of antigen used, approaching more nearly the inhibitory dose than in the case of the Wassermann reaction, and (2) the differentiation between positive and negative reactions, which is not by complete hemolysis or by complete inhibition but is a difference in grades of inhibition. Because of these imperfections, one cannot expect to obtain as consistent results as in the case of the Wassermann reaction, and in consequence nonspecific reactions cannot be entirely eliminated.

It is often stated that a positive test is not obtained in men if the gonococcal infection is confined to the anterior urethra, or in women if the infection is limited to the urethra or vagina.⁴ Most workers are agreed that as complications develop the test becomes positive in an increasingly higher percentage of cases, reaching from 90 to 100 per cent in patients with a complicating arthritis.⁵ From our experience with the complement fixation test in gonorrheal arthritis it would seem necessary to modify the statement that the test is nearly 100 per cent positive in such instances. It is true that all patients in this series who had repeated fixation tests done on blood serums obtained during the time the arthritis was active gave at least one positive test (100 per cent positive). (Case 3 is not included in this series.) However, only 80.7 per cent of the proved cases of active gonorrheal arthritis gave positive tests at all times, and in the probable cases of active gonorrheal arthritis this figure fell to 63.6 per cent. As will be pointed out later, such results depend in part on when in the course of the disease the test was done. There exists considerable variation from case to case as to when the test becomes positive and again negative. In these two groups, 7.7 and 36.3 per cent respectively gave both positive and negative tests. Such results are not surprising when one learns that the clinical records in the later instances reveal that the majority of the negative tests were obtained early in the disease or as the arthritis became quiescent or cured.

The fact that negative tests are not infrequently obtained early in the disease allows one to ask: During what stage of the arthritis does the fixation test become positive? From previous reports it is obvious that antibodies do not accumulate in the blood in sufficient amount until the gonococcal infection has been present at least from ten days⁶ to four weeks. If the disease remains localized, even though it has become chronic, the test may never become positive.⁷ Such localized foci include the urethra, Bartholin's glands and the vagina. The majority of patients in our series did not come under observation until at least several weeks after the onset of the original infection. Furthermore, all our patients were suffering from at least one of the complications of gonorrhea, namely, arthritis, and, as we have already pointed out, the test becomes positive in an increasingly higher percentage of cases once metastasis and complications have resulted. However, one indi-

vidual had a positive test on the day of entry, eleven days after the onset of the arthritis. On the other hand, patients with gonorrheal arthritis entering the hospital five, eight, ten, eleven, sixteen and twenty-four weeks after the onset of the gonorrheal infection had negative fixation tests. In three such instances subsequent tests were done and were found to be positive.

From our experience as well as that of others⁸ it would seem fair to conclude that a persistently positive complement fixation test indicates that the gonococcal focus is still active. In such cases the fixation test may remain positive for months or years. Therefore it is not surprising that one encounters patients with a quiescent or a cured arthritis with serious genito-urinary infection persisting.

Although Osmond¹ and McNeil⁴ originally claimed that a positive test did not occur in a normal individual receiving a gonococcus vaccine, subsequent work⁹ has proved this statement to be incorrect. In fact, certain workers¹⁰ have obtained positive fixation tests in their control subjects by means of five small repeated doses or one large dose of a gonococcus vaccine. The blood serums of such patients may continue to give positive tests for as long as four months. Animal experiments¹¹ indicate that once antibodies are formed in sufficient amounts to give a positive test they may continue to be produced for some weeks after the organisms have disappeared from the circulation. Therefore it must follow that in certain instances of gonococcal infection with or without arthritis the fixation test may remain positive some weeks after a complete cure. None of the patients included in this series were treated with vaccine; therefore this factor cannot account for any of the positive reactions obtained. (In case 2, no fixation test was done after the vaccine was given.)

From the foregoing it is apparent that negative tests may be obtained in certain patients from five to twenty-four weeks after the initial infection, even though a complicating arthritis exists, thus indicating that in an occasional patient antibodies develop very slowly or that the number of organisms entering the system at any one time must not be sufficient in number to stimulate adequate antibody production. From the literature quoted it must also be apparent that a negative test will not be obtained until all antibodies in the blood have been eliminated, even though a complete cure of the original focus has been present for some weeks. Although a negative reaction in a case once positive is fair evidence of a cure, it may represent nothing more than adequate drainage of the original focus. If drainage is adequate, further metastases, necessary to the long continued production of antibodies, do not occur. In such instances a negative test probably means a good prognosis. In this series the appearance of negative reactions usually meant a cure of the arthritic process, and in some it also heralded the cure of the genito-urinary infection.

How is one to account for those cases of proved gonorrheal arthritis contained in this series exhibiting negative reactions? There were six such cases. They can be accounted for in one of several ways: 1. Sufficient tests may not have been done. 2. The tests may

have been done prior to the appearance of the antibodies (in four cases the tests were done on the first, second, fourth and sixth days of the arthritis) or after their disappearance (in two instances the tests were done two and two and one-half years after all joint symptoms had disappeared). 3. The antigen employed in doing our tests may not have been prepared from a sufficient number of the different strains. It will be remembered that our antigen was made from the four major Torrey strains, numbers 8, 15, 32 and 34.

What can be said concerning those cases of proved and probable gonorrheal arthritis which gave both positive and negative reactions? As stated before, most of the negative reactions were obtained early in the disease or as the arthritis became quiescent or cured. Those not explained in this way may represent the previously mentioned errors in the test. However, there were fifteen of the 175 cases of rheumatoid arthritis (8.6 per cent) which also exhibited both positive and negative reactions. Such positive reactions may all be instances of false positive reactions, representing the inevitable errors of the method employed. False positives have been reported by other workers, Chevall¹ obtaining 9.4 per cent in his control series. Some may represent tests done on serums from women in whom a gonococcic focus is often overlooked, even after careful examinations. Such an explanation may well account for the three cases of rheumatoid arthritis (1.9 per cent) which always gave positive reactions. It is interesting in this regard that the group of patients with degenerative arthritis (all being past the age when active gonorrheal infections are ordinarily encountered) all had uniformly negative reactions.

From these data it would seem reasonable to conclude that the gonococcus complement fixation test should be employed in a routine manner as a diagnostic aid in the study of patients suffering from arthritis. If one employs the test in the routine work up of a miscellaneous group of arthritic patients, the fact must be appreciated that if a positive reaction is obtained there is a 10 per cent chance of it representing a nonspecific reaction. The importance of the test lies in the fact that if it is positive it calls attention to the possibility of the arthritis being due to the gonococcus or strengthens a previous suspicion. Having obtained a positive reaction, one should reconsider the history and clinical course of the arthritis and determine whether or not they are consistent with such a diagnosis. In addition, one should make repeated attempts to demonstrate the existence of a gonococcic focus. However, one must realize that a negative reaction fails to rule out a gonorrheal infection in about 20 per cent of the cases. Undoubtedly better results than those recorded here will be obtained if all tests are made at the most favorable time during the course of the arthritis, but this is oftentimes impossible. An improved method would also allow for more accurate results. The weaknesses of the results obtained in our series should serve to stress the point that this laboratory test as employed is only an aid to a careful clinical study of the patient.

CONCLUSIONS

The results in 614 gonococcus complement fixation tests on the serums obtained from 316 patients with various types of arthritis indicate that the test is an important diagnostic aid in routine study of arthritic patients because:

1. Of 125 tests done on the serums from the seventy-four cases of proved or probable gonorrheal arthritis,

81.6 per cent gave positive reactions at some time during the course of the arthritis.

2. Of the tests done on the serums from the fifty-two proved cases of gonorrheal arthritis, 80.7 per cent gave positive reactions at all times.

3. Only 18.4 per cent of all the tests made in the seventy-four proved and probable cases of gonorrheal arthritis were negative.

4. Of 239 cases representing other types of arthritis, 91.6 per cent gave consistently negative reactions.

5. A positive reaction obtained in a case in which the history is not consistent with a diagnosis of gonorrheal arthritis is not significant. In cases in which the history is consistent with a diagnosis of gonorrheal arthritis, a positive test will be correct in 90 per cent of the cases. In about 20 per cent of the cases the reaction will be negative.

If the technical imperfection of the method employed can be improved, it is possible that the gonococcus complement fixation test will approach the Wassermann test in its degree of accuracy.

ORTHOSTATIC HYPOTENSION

THE TREATMENT OF TWO CASES WITH BENZEDRINE SULFATE

PERK LEE DAVIS, M.D.

AND

MARGARET SHUMWAY-DAVIS, M.D.

PHILADELPHIA

Orthostatic hypotension is due to disturbance of function of the sympathetic nervous system. There is an absence of the reflex vasopressor and cardio-accelerator mechanisms necessary to maintain a blood pressure adequate for normal cerebral circulation when a person changes from a supine to an erect position.

Recently Chew, Allen and Barker¹ reviewed the literature on orthostatic hypotension and added six cases. They have carefully analyzed the numerous symptoms and signs exhibited by these people. Syncope and weakness are the most common symptoms dependent on the sudden fall in systolic and diastolic blood pressures when the patient stands. Among the other symptoms listed may be mentioned (1) failure of an increase in the pulse rate when a patient stands, (2) decrease or absence of sweating, (3) loss of libido, (4) pallor, (5) relatively high blood urea and (6) lowered basal metabolic rate.

These authors offer evidence to show that this condition is not due to faulty functioning of the entire autonomic nervous system but to some local disturbance in the peripheral sympathetic nervous supply to the vessels and the sweat glands. They have observed phenomena identical with those seen in orthostatic hypotension after resection of the anterior roots, splanchnic nerves and the lumbar and celiac ganglions.

The purpose of reporting two cases of orthostatic hypotension is to record the results obtained with benzedrine sulfate by mouth.

CASE 1.—A. L., a white man, aged 38, for the past few years had complained of spells of weakness, lightheadedness, blurring of vision and lack of pep. The spells seemed to be most severe while working. His work was of the type necessitating frequent changes in posture and a constant exposure to rather

1. Chew, E. M.; Allen, E. V., and Barker, N. W.: Orthostatic Hypotension: Report of Six Cases and a Review of the Literature, *Northwest Med.* 35: 297-303 (Aug.) 1936.

high temperatures. On one occasion vertigo, nausea and sudden unconsciousness followed a precipitate rise to an erect posture. It was the only severe attack he had had. His wife told him that he appeared as "pale as a ghost." This attack prompted him to seek medical aid. He said that while he worked he rarely perspired but that when he entered cooler surroundings he would perspire as though one had suddenly turned on all the "sweat spigots" at once. Usually after these spells of profuse perspiration he would feel weak. There was no history of tetany. His salt intake was not increased.

The patient was extremely well proportioned, with a height of 71 inches (177.5 cm.) and a weight of 170 pounds (77 Kg.). His skin was extremely dry. Carotid sinus pressure on either side when the patient was in the recumbent or sitting position was unsuccessful in duplicating the symptoms of which he complained. With the exception of the variability observed in the blood pressures and pulse rates (table 1) the physical and neurologic examination proved normal. The laboratory data,

including erythrocyte and leukocyte counts, hemoglobin estimation, flocculation test for syphilis, blood chemistry and urinalysis, were within normal limits. A roentgen study of the chest was reported as normal.

The patient was given 10 Gm. (150 grains) of sodium chloride daily in keratin-coated tablets of 15 grains each. One week later the blood pressure and pulse rate were recorded as previously. Although the patient said he felt improved, no appreciable alteration of the blood pressure was noted.

For the next twelve days, in addition to the sodium chloride, the patient was given 20 mg. of benzedrine sulfate half an hour before rising in the morning and 15 mg. at lunch time. When he reported for observation he stated that he had never felt better and that except for the paradoxical sweating, which was less severe, all symptoms had disappeared. The blood pressure continued to fall when he assumed the erect posture but not to the levels observed before benzedrine sulfate was instituted. In the blood pressure recorded in the recumbent posture there was noted only a slight increase above that recorded previous to the benzedrine sulfate therapy.

In a recent communication the patient states that he has increased the dose. He has found that by taking two 10 mg. tablets at 4 o'clock in addition to the previous doses he feels more comfortable.

CASE 2.—J. L., a white man, aged 40, complained of profound weakness, dizziness, lightheadedness, staggering, dry skin and pallor. He was worried because he had been told that he had a "hidden" cancer. He had been physically tired for the past seven years and profoundly weak for the past eighteen months. There had been no increase in his desire for salt; in fact, he

used less than other members of the family. He stated that he always felt better during the winters; the summer heat seeming to make him worse. He said that he did not perspire very much generally but that his feet were always damp. He rested a great deal of the time because he felt better while recumbent. When he arose and walked around he felt lightheaded and noticed blurring of vision and staggering. He had been troubled with severe constipation all his life. As far as could be determined, a history of the various systems was negative.

The patient was 67 inches (167.5 cm.) tall and weighed 155 pounds (70 Kg.). There was no evidence pointing to myasthenia gravis or Addison's disease. The physical and neurologic examinations were negative except for a variation in the blood pressures and pulse rate on changes in posture (table 2). On two successive tests the basal metabolic rates were recorded minus 16 and minus 10. Other laboratory data, including the Kolmer-Wassermann test, urinalysis, gastric analysis and blood chemistry, were within normal limits. Examination of the blood revealed 4,010,000 erythrocytes per cubic millimeter, 6,240 leukocytes with a hemoglobin estimation of 68 per cent (Dare) and a hypochromic normocytic anemia. Roentgen study of the gastro-intestinal tract was negative except for deep haustrations and a smaller lumen than normal throughout the entire colon.

The patient was placed on sodium chloride in a manner similar to the preceding case. When he was examined ten days later he appeared to be improved. He said that he did not feel as chronically tired as he had, but when he arose quickly or tried to work hard faintness and blurring of vision were about the same. There was no evidence of improvement from the standpoint of more stability in the blood pressure on changes in posture.

For the next eight days benzedrine sulfate in dosage of 25 mg. one-half hour before rising and 15 mg. at lunch time was administered. When he reported back for observation he appeared more alert and stated that his symptoms, although present, were extremely mild and did not inconvenience him in any way. He also stated that constipation no longer bothered him. The blood pressure had increased in the recumbent position and although there was a drop in the pressures when he assumed the erect posture, it did not drop to the level previously recorded.

January 25 I reexamined the patient. The morning dose was increased to 40 mg., the noon dose remains as previously recorded, and it has been necessary to give 15 mg. at 3 o'clock. He was examined February 1 at 5 o'clock. The blood pressure and pulse rate did not seem to vary particularly from those previously recorded, with the exception that the supine blood pressure was 142 systolic, 80 diastolic.

COMMENT

Peoples and Guttman² used benzedrine sulfate in twenty-five cases, obtaining an average of 24 mm. of mercury increase in blood pressure. Tovell,³ in a preliminary report, has used benzedrine to control blood pressure during spinal anesthesia in thirty-one cases with the benefit of a variable degree in all but three cases. Long⁴ recently stated that as a vasoconstrictor benzedrine has an unusually long duration of action. The effects of the drug are regular and constant and are characterized by an increase in pulse amplitude and occasionally in pulse rate. Benzedrine is supposed to have a more gradual action, a more sustained pressor effect, and to dissipate its influence more slowly than other sympathomimetic drugs. Similar pressor effects have been observed in a small percentage of cases of postencephalitis in which the results of benzedrine sulfate therapy are being studied.⁵

Sodium chloride was used empirically in these cases because of the possible influence on the metabolic activity of the adrenal gland. Benzedrine sulfate (phenyl isopropylamine sulfate), a newly developed sympathomimetic drug, is recommended for further investigation in orthostatic hypotension.

SUMMARY

In two cases of orthostatic hypotension, benzedrine sulfate relieved the symptoms of orthostatic hypotension by preventing the fall of blood pressure to the level at which symptoms occurred.

REACTION OF THE BLOOD PRESSURE
OF 400 SCHOOL CHILDREN TO
A STANDARD STIMULUS

EDGAR A. HINES JR., M.D.
ROCHESTER, MINN.

The systemic blood pressure reacts to various forms of external and internal stimulation; consequently, it is subject to considerable variation. This reactivity of the blood pressure can be measured by a standard test in which local cold is used as the stimulus.¹

Excessive variability of the blood pressure may have important significance even though the blood pressure is below accepted maximal levels. Recent studies have indicated that vasomotor reactions, as measured by responses in blood pressure, may be hereditary and that an excessive generalized vasoconstrictor response to stimulation is indicative of a prehypertensive state.¹

Many statistical studies on the blood pressure of children have been carried out in which the usual methods of measuring the levels of blood pressure have

bility of the blood pressure as well as the actual pressure at any given time. Partly as an independent study, therefore, and partly for correlation with a similar study of adults which I am making, I have measured the blood pressure reactions of a group of children to a standard stimulus. As far as I know, such a study has not been made before.

TECHNIC OF TEST

The subject is allowed to rest in a supine position in a quiet room for thirty minutes. During this rest period several readings of the blood pressure are taken until a basal level has been approximated. With the cuff of the sphygmomanometer on one arm, the opposite hand is placed in ice water at 4 C. to a point just above the wrist. Readings of the blood pressure are taken at the end of thirty seconds and again at the end of sixty seconds. The maximal reading obtained while the hand is in the ice water is taken as the index of the response. The hand is removed from the ice water, and readings are then taken every two minutes until the blood pressure returns to its previous basal level. The maximal response frequently occurs within thirty seconds. The blood pressure of subjects with normal levels of blood pressure returns to the basal level within two minutes. On the basis of previous studies, a maximal rise of more than 22 mm. of mercury in systolic pressure and 18 mm. in diastolic pressure was interpreted as being a hyperreactive type of response.

These studies of blood pressure were carried out by testing the children in pairs. Two comfortable beds were placed in a quiet room for the children to lie on. The test was then performed. A standard mercury manometer with a 10 cm. cuff was used to measure blood pressure. Significant emotional disturbances were seldom noted and readings could be made satisfactorily on children as young as 6 years of age. The

* Mean increase for group.

been applied.² There has been considerable disagreement in some of the data obtained by the different investigators. It was felt that some of these differences could be explained on a basis of the latent variability of the blood pressure. Merely to have the blood pressure taken may be a sufficient stimulus to bring it to a maximal level, but since the rise will be maximal in some instances and partial in others the results will not be comparable. For this reason it was believed that it would be of importance to study the range of varia-

test was repeated on forty of the children after a three months interval and no significant variation from the previous test figures was noted.

DATA

The 400 school children whose blood pressures were studied were between the ages of 6 and 19 years; 192 of them were girls, 208 were boys. A summary of the data according to age is presented in the accompanying table. In the group with "normal" (minimal) responses the mean increase was 12.6 ± 0.15 mm. of mercury for the systolic and 14.0 ± 0.16 mm. for the diastolic pressure. In the hyperreactive group the mean rise in blood pressure was 33.8 ± 0.37 mm. for the systolic and 33.8 ± 0.51 mm. for the diastolic pressure. Eighteen per cent of the children had hyperreactions in the systolic and diastolic pressures. There was a much greater lability in the diastolic blood pressure in this group

From the Division of Medicine, the Mayo Clinic.
1. Hines, E. A., Jr., and Brown, G. E.: The Cold Pressor Test for Measuring the Reactability of the Blood Pressure: Data Concerning 571 Normal and Hypertensive Subjects, *Am. Heart J.* 11: 1-9 (Jan.) 1936.
2. Stocks, Percy, and Karn, M. N.: Blood Pressure in Early Life: A Statistical Study, Cambridge, University Press, 1924. Abt, A. F., and Feingold, B. F.: Blood Pressure in Infancy and in Childhood: A Review of the Literature on the Determination of Blood Pressure in Normal and in Pathologic Conditions, *Am. J. Dis. Child.* 40: 1285-1311 (Dec.) 1930.

of children than was noted previously in adults. In many instances the diastolic "range" was equal to or greater than the systolic. This was especially true through puberty up to the age of 16 years, after which there was a decrease in the mean diastolic range. The mean systolic range increased up to the age of 14 years and was then followed by a slight decrease. It is significant that although there was a definite increase in the mean reaction with age there was no significant change in the incidence of hyperreactors in the different age groups. There was no correlation between the responses to the test and the height and weight.

Six pairs of identical twins were tested. The basal readings and responses to the test were almost identical in each pair. In one pair the blood pressure rose from a basal level of 110 systolic and 65 diastolic to 160 systolic and 100 diastolic in one twin, and in the other from 112 systolic and 68 diastolic to 155 systolic and 100 diastolic.

A definite familial trend was noted as the children were grouped into families. The families with the larger number of children were subjected to a more extensive study to determine the significance of the hereditary factor. The result of this study has been reported elsewhere.³

The occurrence of hypertension in the group could not be determined definitely. There is no satisfactory criterion for determining the levels at which hypertension may be said to be present in children.⁴ Only four of the children had blood pressures above the accepted maximal levels for adults; namely, 150 mm. of mercury systolic and 90 mm. diastolic. All of them gave abnormal reactions to the test. Fourteen had blood pressures greater than 140 mm. of mercury systolic and 80 mm. diastolic, and eleven of these were hyperreactors.

In ten of the children there was a very high maximal response to the test. The lowest response to the test was to 170 systolic and 110 mm. diastolic, the highest to 190 systolic and 130 mm. diastolic. There was no history of previous nephritis or evidence of organic heart disease in any of these children.

COMMENT

This study reveals hyperreaction of the blood pressure to a standard stimulus in children as young as 6 years of age. An experiment is being made to determine whether the incidence of hyperreactors in this group of children correlates with the combined incidence of hypertension and hyperreactors among adults.

There was a definite increase in the mean blood pressure reactions in the prepuberty and puberty age groups. This agrees with other studies on levels of blood pressure.

SUMMARY AND CONCLUSIONS

A study of the blood pressure reactions to a standard stimulus of 400 school children revealed that 18 per cent of them were hyperreactive in respect to systolic and diastolic blood pressure. The reaction of the blood pressure increases during the prepuberty and puberty period, but the incidence of hyperreactors was found to be approximately the same in the different age groups. The reaction of the diastolic blood pressure is much greater in children than in adults.

PROTAMINE INSULIN IN JUVENILE DIABETES

CLINICAL OBSERVATIONS

H. R. DRYSDALE, M.D.

ROCHESTER, N. Y.

The number of published reports on the chemistry, character and clinical observations of protamine insulin are already becoming voluminous. The claims made for this combination by its discoverers,¹ namely, that protamine insulin offers a prolonged pharmacologic action with comparative freedom from hypoglycemic reactions and a subsequent diminution in the number of daily injections required for diabetic control, have been fully confirmed by investigators on this continent.² Scott,³ Fisher and Rabinowitch⁴ have recently demonstrated that the addition of zinc to protamine insulin produces an even more prolonged action of the combination on the blood sugar content of both diabetic and nondiabetic subjects and it is suggested by Rabinowitch⁴ that the addition of zinc to the protamine insulin increases the sensitivity of the individual to the injected insulin; he has also demonstrated that the addition of zinc to crystalline and even to the regular commercial insulin produces a more prolonged pharmacologic action. While calcium has been employed also as a stabilizing factor in the formation of the protamine insulin complex, it would appear in the light of current investigation that zinc will be the element of scientific choice for this rôle in the future. The present discussion will attempt only to set forth our clinical observations on the use of protamine insulin as contrasted to regular commercial insulin.

This study, commenced early in July 1936, is based on the observations of ten juvenile diabetic patients who were carefully selected with regard to the following qualifications: (1) a juvenile diabetic patient (under 21 years of age); (2) an intelligent and cooperative subject; (3) an uncomplicated case (where possible); (4) a patient requiring insulin for diabetic control. As will be seen from the records summarized herein, most of these patients present relatively severe diabetes mellitus. The results have been most encouraging. Contrary to the rather general written opinion that protamine insulin should be used initially only under hospital observation,⁵ it has been found that hospitalization is not essential in shifting patients from

Helpful cooperation in this work was given by Dr. C. B. F. Gibbs. The protamine insulin used in this study was supplied through the generosity of Eli Lilly & Co. and E. R. Squibb & Sons.

regular insulin to protamine insulin, but it is my opinion that hospital study during this transition greatly facilitates and shortens the period of "semicontrol" that may be expected. In this series, four of the ten patients were hospitalized, cases 7, 8, 9 and 10, but it is felt that cases 7 and 8 might have been very satisfactorily shifted to protamine insulin without such close study, although certainly a much more accurate and definite picture and hence a greater feeling of relief for the physician is available through hospitalization.

TIME OF INJECTION OF INSULIN

In view of the fact that the patients to be studied were juveniles and most of them were of school age, it was felt that before breakfast was the ideal time for the administration of protamine insulin. The observations of Sprague, Blum and their associates² were a great help in making this choice of time. Consequently, it was arbitrarily decided to give all insulin before breakfast, the protamine insulin being given one hour before breakfast and any required supplemental dose of regular insulin being given the usual twenty minutes before breakfast. Subsequent observations and reflections on the definitely prolonged action of protamine insulin have led to the opinion that it may be given at any time before breakfast, as its effect obviously persists at least twenty-four hours; but it is felt that whether the time is one hour before breakfast or twenty minutes before breakfast it is best to employ the same time each day.

Until early September six of the patients were taking varying supplemental doses of regular insulin, but this inconvenience has apparently been overcome so that none of our ten cases at present require such. It has been our observation that the period of highest blood sugar level and subsequently greatest glycosuria is after breakfast under protamine insulin routine, and such condition can be readily controlled by supplying the required dosage of supplemental regular insulin before breakfast.

ESTIMATING THE DOSE

The plan followed with each individual case at the institution of protamine insulin has been to give an amount of this substance equal to the combined number of units of regular insulin previously required over a twenty-four hour period. While in several of these cases the insulin requirements have apparently been heavier under the new regimen than under the old, it was quite obvious that many of these patients never represented twenty-four hour daily control of their diabetes in the past. In short, although they were progressing with relatively smaller doses (twenty-four hours) of insulin they were never theoretically perfectly controlled diabetic patients, and when one considers the potential complications of the disease it is easier to appreciate the tremendous advantage to be gained in employing the new insulin especially in juvenile diabetes.

In general, it is my opinion that ample doses of protamine insulin should be given initially, i. e., when the patient is transferred from the old insulin to the new, and that the dose may be reduced if necessary. Such a procedure tends to eliminate the prolonged period of "transitional glycosuria" which has been so frequently observed when apprehension concerning the early giving of massive doses exists. The relative rarity of insulin reactions with protamine insulin allows one to assume this attitude when instituting the new insulin.

DIET

Dietary regulation in the ten cases studied has been essentially an individual factor. It was felt that although from a theoretical point of view giving but 20 per cent of the daily carbohydrate intake at breakfast would tend to less need for supplemental doses of regular insulin, on the other hand, the natural desire and need of a school child for an ample breakfast was considered and it was decided to continue the diets as they were; that is, roughly one third of the daily carbohydrate being given at each meal. As this study has progressed, a general gradual shift in all diets toward the high carbohydrate-low calory type is being achieved and it would seem that protamine insulin is highly efficacious under such a dietary regimen.

REACTIONS

Insulin reactions under protamine insulin have been characterized by their rarity and usually mild symptomatology, but there is a definite tendency for their onset to be most insidious. Four of our patients have experienced hypoglycemic reactions during this study, but the only severe reaction observed occurred in case 6 and is described in the history. Although "unconsciousness" occurred, the attack quickly passed off following the taking of orange juice; obviously the patient was not unconscious but appeared so to a fond parent. There have been no recurrences in this case. It is interesting to note that the blood sugar in case 9 reached a low ebb of 45 mg. without producing symptoms of hypoglycemia except for rather ravenous hunger. Also, case 4 presented a known blood sugar of 37 mg. on one occasion without symptoms of hypoglycemia. In case 5 the only reactions recorded occurred in midafternoon while the patient was taking a supplemental dose of regular insulin to control after breakfast glycosuria; there have been no recurrences in this case since the abolition of regular insulin.

SUBJECTIVE IMPROVEMENT

Without exception, the ten patients studied in this series have remarked on how much better they feel under the new regimen of insulin administration. It has not been necessary to interrogate the patients on this point, as they have all voluntarily expressed enthusiasm for what they feel to be a new era in their existence. While some of the enthusiasm might be explained on the basis of the greater convenience to the patients, in that they may lay aside their insulin syringes before breakfast for the ensuing twenty-four hours, several have voiced the opinion that they feel they are more like "normal human beings." Parents of the juveniles have also been most enthusiastic, especially the parents of patient 10, who said that their son was "the best they have seen him in six years." Many of these patients have noticed a definite increase in appetite under protamine insulin, and the high carbohydrate-low calory diet should be a welcome solution of this problem.

CASE HISTORIES

The following summaries are presented to give in condensed form the brief past history and essential picture of these patients under protamine insulin. All superfluous details have been omitted, but it is hoped that a fairly comprehensive picture is obtainable of the individual results in this study.

CASE 1.—*History*.—T. L. V., a white girl, aged 7½ years, first developed symptoms of diabetes in April 1936. Polyuria, polydipsia and polyphagia increased and during the last three weeks

of July there was a loss of 3 pounds (1,360 Gm.). The onset of the illness had been insidious with no preceding infection, and there was no familial history of diabetes mellitus. Physical examination when first seen July 29 was essentially negative except for some undernutrition. The weight at that time was 38 pounds (17.2 Kg.) and the urine showed a 4 plus Benedict reaction and 2 plus acetone. The fasting blood sugar then was 186 mg.

The patient was put on a diet of 1,800 calories (protein 70 Gm., fat 90 Gm., carbohydrate 180 Gm.), and insulin 10-0-10 was instituted. August 1, fasting blood sugar was 263 mg. and insulin was raised to 15-0-10. August 6, the weight was 39 $\frac{3}{10}$ pounds (18 Kg.) and because of rather persistent glycosuria regular insulin was again increased to 15-0-15 with an increase in diet to 1,972 calories (protein 73 Gm., fat 96 Gm., carbohydrate 204 Gm.). August 12 the weight was 40 $\frac{1}{2}$ pounds (18.4 Kg.) and the insulin requirement was 17-0-15, and occasional glycosuria was still present during the day.

Protamine Insulin Record.—Protamine insulin was instituted August 17, with a dosage of 25 units given one hour before breakfast. During the period from August 17 to August 21 there was occasional 1 plus glycosuria during the day but by August 23 the urine had become completely sugar free for twenty-four hours and continued to be so. August 26 there was a moderately severe insulin reaction occurring at noon, which was characterized by an insidious onset but was relieved by the oral administration of dextrose. The protamine insulin dosage was subsequently reduced to 15 units. Under this routine the patient continued to be essentially sugar free, showing on occasion a 1 plus glycosuria. September 1 protamine insulin dosage was reduced to 10 units and the child continued to show only an occasional 1 plus sugar reaction. September 11 the protamine insulin dosage was reduced to 9 units and on September 19 to 8 units, at which level it has remained until the present time. The weight, September 19, was 42 $\frac{3}{10}$ pounds (19.2 Kg.), and the fasting blood sugar on that day (taken one hour after 8 units of protamine insulin had been given) was 72 mg. The patient has continued to be essentially sugar free under what may be considered a comparatively minimal dose of protamine insulin. Whereas prior to the institution of protamine insulin she required 32 units of regular insulin she now requires one fourth such dose in protamine insulin and is in all respects a perfectly controlled juvenile diabetic patient. The parents are most enthusiastic over protamine insulin and no supplemental dose of regular insulin has ever been necessary. The convenience of administration of protamine insulin makes itself more obvious in a patient of this age, in which a marked fear of hypodermic injection is generally the rule and multiple injections present quite a problem to the parents.⁶

CASE 2.—History.—R. L., a white girl, aged 14, has always been thin and undernourished in appearance, presenting in many ways the cardinal aspects of the asthenic diathesis. Diabetes mellitus was first diagnosed in 1926 at the age of 4 years, at which time a history was obtained of one year of polyuria and nocturia. During the past ten years there have been three hospital admissions to the Rochester General Hospital for the control of her diabetes. The patient has been on regular insulin since 1927, her insulin "requirements" varying from 5-3-3 to 10-0-10. Briefly summarized, her diabetic history has been one of almost persistent glycosuria and high blood sugar levels after eating, all values approximately between 250 to 300 mg. For the past year the diet had been approximately 2,000 calories (protein 80 Gm., fat 112 Gm., carbohydrate 170 Gm.) but no marked gain in weight had occurred.

Protamine Insulin Record.—Protamine insulin was instituted Aug. 13, 1936, the initial dose being 12 units taken the usual one hour before breakfast, the patient being instructed to raise the insulin to make herself sugar free in the fasting morning specimen. The blood sugar three hours after eating following 10 units of regular insulin was 290 mg. and the fasting urine 1 plus and the urine three hours after eating 3 plus, the patient having been on insulin 10-0-10. The weight August 13 was 62 pounds (28 Kg.). August 20 she was taking protamine insulin 17 units and regular insulin 5 units (twenty minutes before breakfast). Fasting urines were 1 plus, urines one hour after breakfast were negative, occasional glycosuria being evidenced at other times during the day. The blood sugar after meals was 334 mg. The patient was instructed to increase the

protamine insulin. August 27 the patient stated that she was taking 18 units of protamine insulin and did not require regular insulin. Fasting urines had been negative. A urine specimen taken two hours after eating was 3 plus and blood sugar two hours after eating was 512 mg. September 3 she was taking protamine insulin 20 units and regular insulin 5 units, and all fasting urines were negative. Two hours after breakfast the urine was 3 plus and the blood sugar 350 mg. September 11 the patient was on the same insulin dosage as September 3, although she had been instructed to increase the protamine insulin to 25 units and the supplemental dosage of regular insulin as required. Fasting urines were all negative, but two and one-half hours after breakfast the urine was 1 plus and blood sugar 234 mg. September 17 the weight was 64 $\frac{1}{2}$ pounds (29.3 Kg.). She had been taking protamine insulin 25 units and no regular insulin, was sugar free twenty-four hours a day, and the blood sugar two hours after breakfast was 151 mg.

Since January 1936 the patient has been receiving 2.5 cc. of a commercial preparation of the pituitary growth hormone (antuitrin-G) weekly; her height in January 1936 was 57 inches (145 cm.) and her present height is 59 inches (150 cm.).

It would appear that this child's diabetes is under perfect control on 25 units of protamine insulin. She states that she feels very well, is gaining weight, has experienced no insulin reactions and is most appreciative of the fact that she is finished with the hypodermic injection of her insulin before breakfast. The difficulty experienced in this case was attempting to get the patient to elevate her single injection of protamine insulin to her proper maintenance dose by herself.

CASE 3.—History.—T. C., a white youth aged 16, had a sudden acute onset of diabetes mellitus about January 1936. He was in Strong Memorial Hospital from January 28 to February 11, for control of his diabetes, and persistently high blood sugars were the rule while in the hospital. His diet since that time has been protein 90 Gm., fat 110 Gm. and carbohydrate 210 Gm.

The patient was followed in the diabetic clinic of Strong Memorial Hospital after February 1936, and his insulin requirements until June were 20-0-10-5 (the five units being given at midnight). In June the insulin was changed to 20-0-15. The after-meal blood sugars under the 20-0-10-5 routine varied between 100 and 170 mg. while the after-meal blood sugars (morning) under the 20-0-15 routine varied between 204 and 258 mg. After June the patient usually evidenced glycosuria before breakfast, but when he had been taking 5 units of insulin at midnight he was sugar free in the fasting urine specimen.

Protamine Insulin Record.—Protamine insulin was instituted July 14, at which date his weight was 120 pounds (54.4 Kg.). He was put on protamine insulin 30 units with no supplemental regular insulin. On July 21 protamine insulin was continued at 30 units and 5 units of regular insulin recommended because of considerable after breakfast glycosuria. On this date the after-meal blood sugar was 244 mg. July 28 the weight was 118 pounds (53.5 Kg.) on 35 units of protamine insulin and 8 units of regular insulin and there was still considerable after-breakfast glycosuria, but fasting urines were negative. The blood sugar after meals was 276 mg. August 4, the weight was 116 (52.6 Kg.) and he was taking protamine insulin 35 units and no regular insulin, with occasional 1 plus glycosuria after breakfast. The blood sugar after meals was 282 mg. August 18, the weight was still 116 pounds, and he was taking protamine insulin 40 units and regular insulin 5 units and stated that after-breakfast glycosuria persisted. The blood sugar after meals was 310 mg. (At this time the patient had a slight infection in his left index finger). August 25, the weight was 117 pounds (53 Kg.) and he was taking protamine insulin 42 units and regular insulin 5 units. The urines were now essentially negative. The blood sugar after eating was 235 mg. September 8, the weight was 118 pounds on 45 units of protamine insulin and 8 units of regular insulin. At this time the patient had a slight head cold and all urines had been 1 plus. September 22 the weight was 120 pounds (54.4 Kg.) and he was taking protamine insulin 45 units with no supplemental regular insulin, and he was sugar free twenty-four hours a day.

The patient has been on a diet of protein 100 Gm., fat 100 Gm., carbohydrate 175 Gm. since the institution of protamine insulin. He stated that he felt fine and that there had been no insulin reactions, but it was difficult to get him to elevate his

6. This case is presented through the courtesy of Dr. Einar Lie.

insulin to the proper maintenance level. He has gained only 1 pound (453 Gm.), but it must be remembered that the diabetes was reasonably well controlled under regular insulin before protamine insulin was instituted. It is also interesting to note that the infection of the upper respiratory tract of September 8 produced no evidence of acidosis, nor did it set him back in his progress.

CASE 4.—History.—T. L., a white youth aged 19, intelligent and cooperative, had diabetes which was first diagnosed in 1930 at the age of 13. Between 1930 and 1932 there were four admissions to the Strong Memorial Hospital, during which time the patient had an acute glomerular nephritis and a phrenicotomy for bronchiectasis, which was done in June 1931 with marked relief of symptoms of this disease. He had had occasional chest colds since, which always necessitated marked additional amounts of regular insulin and were usually accompanied by mild acidosis. The patient had required insulin since the onset of diabetes in 1930, the dosage in 1931 being approximately 10-0-10 during health but rising to as much as 100 units a day in divided dosages when infection was present. During 1933 the insulin requirements varied from 40 to 55 units per day in divided doses. During 1934 and 1935 there were no severe respiratory infections and the average insulin requirements were 35-0-20. Postprandial blood sugars between 1931 and 1935 varied between 200 and 300 mg. His weight in 1931 was 97 pounds (44 Kg.), in 1932 112 pounds (51 Kg.), in 1933 130 pounds (59 Kg.), in 1934 138 pounds (62.6 Kg.) and in 1935 150 pounds (68 Kg.).

Protamine Insulin Record.—July 15, 1936, protamine insulin was instituted. On July 14 the four hour postprandial blood sugar after 35 units of regular insulin was 228 mg. At this time the patient was showing a 1 to 2 plus glycosuria in the before breakfast specimen and had been taking regular insulin 35-0-20. His weight July 14 was 166 pounds (75 Kg.). He was started on 45 units of protamine insulin taken one hour before breakfast with no other insulin and was instructed to increase the protamine insulin as required and to supplement with regular insulin if necessary. He returned to the clinic July 28, at which time he was taking protamine insulin 55 units and regular insulin 10 units before breakfast and was usually sugar free in the specimen before breakfast. The two and one-half-hour blood sugar after eating was 222 mg. and the weight was 171 pounds (78 Kg.). August 18 he was taking protamine insulin 60 units and regular insulin 10 units. The patient stated that he occasionally had a faint trace of sugar in the before breakfast specimen but was sugar free the rest of the time. The blood sugar taken on this date after eating was 37 mg. and there were definitely no symptoms of insulin reaction. His weight was 175 pounds (79 Kg.). He was advised to discontinue regular insulin and to continue on the same dose of protamine insulin. He continued to feel well; there were no insulin reactions and he was sugar free at all times until early in September, when a severe respiratory infection developed that was characterized by fever of moderate degree and a very productive cough. He received no professional attention during this illness, which persisted for two weeks. He stated that he took only one half of his regular diet, which was protein 100 Gm., fat 80 Gm. and carbohydrate 160 Gm., and took protamine insulin 40 units and regular insulin 10 units, both being taken before breakfast. At no time during the illness was there any evidence of acidosis, but at times there was considerable glycosuria. September 22 he returned to the clinic, on which date his weight was 178 pounds (81 Kg.) and he stated that during recent days he had been taking 60 units of protamine insulin before breakfast, which maintained him sugar free twenty-four hours a day. It is interesting to note that again in this case, in which infection would be expected to produce a varying degree of diabetic acidosis, there was no sign of such a condition being present. The patient in two months under protamine insulin has gained 12 pounds (5.4 Kg.) in spite of a two weeks illness, and there has been marked subjective improvement under protamine insulin.

CASE 5.—History.—D. S., a white girl, aged 18, intelligent and cooperative, first developed diabetes in 1931 at the age of 13, the onset being acute in character over a period of six weeks with loss of weight, polyuria and the like. She was in Strong Memorial Hospital from July 31 to Aug. 15, 1931, for control of the diabetes and has subsequently been followed in

the diabetic clinic of that hospital. In the latter part of June 1933 there was a ten day admission to the hospital for gastroenteritis, which was complicated with diabetic acidosis. The patient has been on insulin since the onset of her diabetes and the clinical records revealed a persistent high blood sugar level with almost constant glycosuria until 1936, when she stated that she was essentially sugar free on regular insulin 20-0-20 and a self-regulated diet of protein 70 Gm., fat 60 Gm., carbohydrate 80 Gm. She has insisted for the past year that she could not eat any more than this allowance, and there has never been any reason to doubt the veracity of the patient.

Protamine Insulin Record.—Protamine insulin was instituted July 28, 1936, the patient being put on 35 units of protamine insulin with no supplemental insulin, with instructions to increase the protamine insulin and supplement with regular insulin if necessary. Her weight at this time was 143 pounds (65 Kg.). August 4 she was taking protamine insulin 40 units and regular insulin 5 units and stated that she was showing from 2 to 3 plus glycosuria at all times. The three hour blood sugar after eating was 253 mg. and the weight was 143 pounds (64.9 Kg.). August 11 she was taking protamine insulin 45 units and regular insulin 9 units and she stated that urines were 1 plus before breakfast and that there was still considerable glycosuria after breakfast and before lunch. The blood sugar two hours after breakfast was 247 mg. and she weighed 144 pounds (65 Kg.). August 25 she was taking protamine insulin 50 units and regular insulin 20 units, and she stated that the urine still showed 1 plus sugar before breakfast, with a 3 plus glycosuria after breakfast. The blood sugar two hours after food was 270 mg. and she weighed 144 pounds (65 Kg.). September 1 she was taking protamine insulin 65 units and regular insulin 25 units and was sugar free twenty-four hours a day. The blood sugar two and one-half hours after food was 127 mg. and the weight was 146 pounds. The patient stated that she was feeling very well. September 8 she was taking protamine insulin 70 units and regular insulin 25 units. She had increased the protamine insulin because of 1 plus glycosuria in the before breakfast specimen for three days, but there was no glycosuria during the remainder of the day; the weight was 148 pounds (67 Kg.). September 15 she was still taking protamine insulin 70 units and regular insulin 25 units and was sugar free twenty-four hours a day. The patient was advised at this time to reduce the dosage of regular insulin as much as possible. The weight was 152 pounds (69 Kg.). September 26 the patient was taking protamine insulin 80 units and no supplemental regular insulin. She stated that she had had three mild insulin reactions occurring in the late afternoon during the past week while taking a supplemental dose of 10 units of regular insulin along with 70 units of protamine insulin. She is now free from glycosuria on protamine insulin 80 units without any supplemental dose of regular insulin and is feeling perfectly well. Her weight, September 26, was 150 pounds (68 Kg.).

The patient presented a rather complicated problem in that her condition was apparently controlled before the institution of protamine insulin on regular insulin 20-0-20, but at the present time she requires twice the unit dosage in protamine insulin. She states, however, that she feels much better under this new routine than she did prior to the institution of protamine insulin. She has gained 7 pounds (3,175 Gm.) on a very low calory intake (which gain in weight has annoyed her somewhat as she has the antipathy characteristic of her sex in regard to gaining weight), but she volunteers the remark that she "feels much better in all ways than she did in the past."

CASE 6.—History.—J. J., aged 13, a very intelligent white girl, first developed signs and symptoms of diabetes mellitus two years before at the age of 11, the onset being sudden in character. She had had two admissions to the hospital, the first one being in January 1935, at which time her fasting blood sugar varied between 374 and 184 mg. While in the hospital insulin had been 35-15-30, which was reduced on discharge from the hospital to 35-0-30. She was subsequently followed in the diabetic clinic of the Rochester General Hospital during 1935, her insulin requirements averaging 30-0-30. It was noted that her blood sugar after food usually exceeded 250 mg. In September 1935 she was again admitted to the hospital in moderately severe diabetic acidosis, which complicated an acute infection of the upper respiratory tract. Following eighteen

days in the hospital she was discharged on insulin 30-10-15. Her last and final fasting blood sugar during this admission was 204 mg. She was subsequently seen at various intervals in the diabetic clinic; her weight in January 1936 was 85 pounds (38.6 Kg.). The diabetes seemed to be clinically controlled, but it is to be noted that blood sugar taken two hours after food January 30 and May 28 were 534 mg. and 440 mg. respectively. Her insulin dosage during the period from January to August 1936 when protamine insulin was instituted averaged 25-0-25; also during this interval considerable glycosuria had usually been present at various times during the day, but no infectious complications had arisen.

Protamine Insulin Record.—August 6, protamine insulin was instituted. Her weight on this date was 90 pounds (41 Kg.) and a blood sugar specimen two and one-half hours after food (following the injection of 25 units of regular insulin twenty minutes before breakfast) was 204 mg. The urine taken at the same time as the blood sugar showed a trace of sugar. She was put on protamine insulin 40 units one hour before breakfast and regular insulin 10 units twenty minutes before breakfast. The patient was sent home with instructions to return to the clinic in one week and to increase the protamine by units of 5 as necessary to produce a negative fasting urine in the morning; the regular insulin to be increased by units of 2 to control after-breakfast and before-lunch glycosuria. August 13 the weight was 91 pounds (41 Kg.) and glycosuria was 1 plus on most specimens, including fasting. The patient was taking 50 units of protamine insulin and 12 units of regular insulin before breakfast and hesitated to raise the insulin intake further, the blood sugar two hours after food being 250 mg. She was instructed to continue increasing protamine insulin and regular insulin as required. August 20 the weight was 92½ pounds (42 Kg.). She had been taking protamine insulin 55 units and regular insulin 16 units and was now sugar free in the fasting morning specimen but usually showed a 3 plus after-breakfast glycosuria. Blood sugar after meals was 114 mg. August 27 the weight was 94 pounds and she was taking protamine insulin 60 units and regular insulin 14 units. She was sugar free twenty-four hours most of the time, and blood sugar two and one-half hours after meals was 296 mg. The patient definitely had no glycosuria when this blood sugar was taken. September 3 she weighed 95½ pounds (43 Kg.) on 60 units of protamine insulin and 16 units of regular insulin. Fasting urines were always negative, occasionally 1 plus urine after breakfast. Blood sugar two hours after meals was 244 mg. The patient continued on the routine protamine insulin 60 units and regular insulin 16 units until September 11, at which time a subacute infection of the upper respiratory tract developed with a temperature of about 100 F. Urines became from 2 to 4 plus for sugar throughout the day. The patient was put to bed at home and protamine insulin dosage was maintained at 60 units, while regular insulin before breakfast was raised to 20 units and 20 units of regular insulin was given before supper. Fever continued until September 15, but glycosuria persisted, so supplemental doses of regular insulin were continued. September 17 she felt "peculiar" on arising; she took protamine insulin one hour before breakfast but no regular insulin, and when she was about to eat breakfast she suddenly became "unconscious," slumping to the floor, but the parent was able to get the patient to swallow some orange juice. In about ten minutes she became conscious and was very emotionally upset but took her breakfast. This was felt to be an insulin reaction, although glycosuria of 3 plus had been present on the same morning. The glycosuria at this time may be explained by the fact that the patient had not voided since 9 p. m. the previous evening, at which time the urine had been 3 plus. There was no evidence of acidosis at any time during the period of the infection of the upper respiratory tract. September 19 the insulin requirements had returned to protamine insulin 60 units and regular insulin 16 units. Her weight September 19 was 97 pounds (44 Kg.). September 26 there was still moderate glycosuria and a slight nasal discharge, but her weight was 101 pounds (46 Kg.).

It is interesting to note that one year previously this patient had an almost identical infection of the upper respiratory tract and had promptly gone into diabetic acidosis as a result, while this time there was no evidence of acidosis but a rather severe insulin reaction during convalescence. She has been on a diet of protein 80 Gm., fat 90 Gm., carbohydrate 170 Gm. and has

gained 11 pounds (5 Kg.) since the institution of protamine insulin. She has evidenced marked subjective improvement and states that she "never felt better in her life."

CASE 7.—History.—M. K., a white girl, aged 17 years, had a sudden onset of diabetes mellitus in 1933 (at the age of 14). Her past history included a guillotine amputation of the left arm for a *Bacillus welchii* infection which followed a compound fracture of the left radius and ulna at the age of 11. In 1935 reamputation of the stump was necessary. This admission, however, had nothing to do with the diabetes. During 1933 the diabetes was fairly well controlled on very small doses of regular insulin, the average dose being 5 units before breakfast. By 1935 her insulin requirements had risen to 30-0-30, her diet during the past two years averaging protein 80 Gm., fat 90 Gm., carbohydrate 170 Gm. Her postprandial blood sugars during 1935-1936, taken at odd times in the diabetic clinic, all exceeded 300 mg., and her weight in February 1935 was 110 pounds (50 Kg.) and in January 1936 was 103 pounds (46.7 Kg.), and she had continued during the current year to fail to gain weight. Her weight on admission to the Rochester General Hospital, July 16, was 97 pounds (44 Kg.).

Protamine Insulin Record.—The patient was admitted to the hospital July 16, at which time she had been (for three months) on protein 60 Gm., fat 110 Gm., carbohydrate 140 Gm., insulin dosage having been 30-0-30. The fasting blood sugar under regular insulin was 320 mg. The same diet was continued and protamine insulin 55 units was given one hour before breakfast, blood sugars being taken at 8 a. m. (fasting) and 8 p. m. daily. While in the hospital under protamine insulin the fasting blood sugars fell in forty-eight hours to normal values; namely, 85, 80 and 85 mg. The 8 p. m. blood sugars varied between 190 and 205 mg. During her hospital stay there was a tendency toward after-breakfast and before-lunch glycosuria but the remainder of the day the patient was sugar free under protamine insulin; no insulin reactions occurred and she was discharged from the hospital July 23 under a continued dosage of 55 units of protamine insulin with instructions to take 5 units of regular insulin twenty minutes before breakfast in an attempt to control the after-breakfast glycosuria.

Subsequent History.—July 30 the patient weighed 100 pounds (45.4 Kg.), now taking protamine insulin 50 units, regular insulin 5 units; urines were negative fasting and 3 plus after breakfast. The blood sugar after food was 266 mg. August 6 the weight was 102½ (46.5 Kg.) on protamine insulin 55 units, regular insulin 5 units, and she continued to be sugar free in fasting urines but showed 1-2 plus glycosuria after breakfast. The blood sugar after food was 392 mg. and the patient was instructed to increase regular insulin. August 13 the weight was 107 pounds (48.5 Kg.); she states that she is continuing on protamine insulin 55 units and regular insulin 5 units because she is sugar free twenty-four hours a day. The blood sugar two hours after food was 364 mg. August 20 the weight was 107½ pounds (49 Kg.) and she was taking protamine insulin 55 units and regular insulin 7 units; she stated she was sugar free twenty-four hours a day. On this visit the patient volunteered the remark that she felt "the best she had ever felt." September 3 she weighed 110 pounds (50 Kg.) and was taking protamine insulin 55 units and regular insulin 5 units; she stated that she continued to be sugar free twenty-four hours a day, yet the blood sugar that morning after food was 488 mg. The patient was advised to increase protamine insulin to 60 units and discontinue regular insulin. September 12 on the aforementioned dosage the weight was 111 pounds (50 Kg.) and the patient stated that she was sugar free twenty-four hours a day and was feeling perfectly well.

In this case it is rather difficult to evaluate the relatively high blood sugars with the steady freedom from glycosuria. I hope in the near future to determine accurately just where the renal threshold value is in this case. There has never been any reason to doubt the veracity of the patient, who is very intelligent and highly cooperative and is well versed in her condition. In this case, excluding the blood sugar readings, there has been marked clinical improvement as evidenced by the gain of 14 pounds (6.4 Kg.) since the institution of protamine insulin and a marked subjective improve-

ment as evidenced by the patient's various remarks. It would seem from the observation in this case that the only period of high blood sugar value must be between breakfast and lunch.

CASE 8.—History.—M. B., a very intelligent and cooperative white youth, aged 16, had an acute onset of diabetes mellitus in 1932 at the age of 12 years, the condition appearing shortly after convalescence from acute scarlet fever. During the period from 1932 to 1936 there had been two admissions to the Strong Memorial Hospital for severe diabetic acidosis, the last admission being in February 1936, at which time the carbon dioxide combining power was 17 volumes per cent. For the past six months this patient had been on a diet of protein 100 Gm., fat 100 Gm., carbohydrate 175 Gm., and during that period he had been taking insulin 27-25-35 and the diabetes was perfectly controlled except for a fasting urine glycosuria the control of which had not been attempted with an insulin injection at 1 a. m. The patient was admitted to the hospital on August 27.

Protamine Insulin Record.—The patient was kept on the diet previously mentioned and 80 units of protamine insulin was given one hour before breakfast and 20 units of regular insulin twenty minutes before breakfast. The fasting blood sugar before the institution of protamine insulin was 542 mg. and blood cholesterol was of normal value. During the first day under protamine insulin the urines were 4 plus for sugar on all specimens until before supper, when the Benedict reaction dropped to a trace and after supper the urine was negative. The 8 p. m. blood sugar was 165 mg. August 26, under the same insulin dosage as the previous day, fasting blood sugar was 80 mg. and the 8 p. m. blood sugar was 178 mg. On this day the patient was sugar free twenty-four hours. August 27, 80 units of protamine insulin and 10 units of regular insulin were given, the fasting blood sugar this day being 82 mg. and the 8 p. m. blood sugar 185 mg. and the patient showed a 2 plus Benedict reaction before supper and a 1 plus after supper, a trace of urine sugar having been present before lunch. August 28 the fasting blood sugar was 58 mg. and the patient was given protamine insulin 80 units and regular insulin 15 units. He was entirely sugar free during the day and was discharged from the hospital that evening. August 29, 80 units of protamine insulin was given and 10 units of regular insulin, and a trace of sugar was present in the fasting and after-breakfast specimens, no sugar being present for the remainder of the day. August 30 the supplemental dose of regular insulin was discontinued and on this day the patient was perfectly sugar free.

He has been carried on 80 units of protamine insulin since that time and is apparently perfectly controlled and had shown no evidence of glycosuria to September 26. His weight had increased from 110 pounds (50 Kg.) on March 21, to 124 pounds (56 Kg.) on Aug. 21, 1936. Since the institution of protamine insulin he has continued to gain and now weighs 126 pounds (57.2 Kg.). The patient has experienced no insulin reactions and no untoward local reaction from the admission of protamine insulin at a single site of injection. He feels perfectly well and is most pleased with the elimination of multiple insulin injections.

CASE 9.—History.—M. C., a white girl, aged 20 years, in whom diabetes first developed in 1926 at the age of 10 years, has presented one of the most persistently difficult control problems encountered both in the hospital and in the diabetic clinic of Strong Memorial Hospital. She had had eight previous hospital admissions during this ten year period in which diabetes played the major rôle. In 1934, because of a questionable chronic frontal sinusitis, a partial turbinectomy, bilateral, was done, and in December 1935 a turbinectomy, middle right, and an ethmoidectomy, anterior right, were done because of chronic right ethmoiditis. In spite of this extensive nasal surgery and the apparent clearing up of chronic foci of infection in the upper respiratory tract, the patient continued to show marked glycosuria at all times in spite of large doses of insulin given four times a day (before each meal and at 1 a. m.). She had never been too cooperative a patient, partly because of a feeling of despair with her persistent glycosuria in spite of large doses of insulin and strict dietary cooperation during varying periods of her diabetic history. She frequently exhibited signs of mild acidosis and never felt or considered herself to be really well. Her blood sugars after food taken

at fairly regular intervals since 1934 varied between 200 and 500 mg., the general average being well over 300 mg., and there was a constant 2 to 4 plus glycosuria. At each visit to the clinic positive diacetic and acetone urine reactions were the rule rather than the exception, and such changes were constant during all mild infections of the upper respiratory tract, to which the patient is most susceptible. Various dietary routines had been tried without success in the control of this patient. She was admitted to Strong Memorial Hospital August 27 for protamine insulin control. Her diet had been protein 70 Gm., fat 90 Gm., carbohydrate 100 Gm., because of persistent anorexia. Her weight since May 1936 had varied between 122 and 125 pounds (55.3 and 56.7 Kg.). She had been taking regular insulin 36-32-30-34 (the 34 units being given at 1 a. m.), and the urine specimen taken late the evening of admission to the hospital showed a 4 plus sugar and a 3 plus acetone reaction. The weight on admission was 121 pounds (55 Kg.) and physical examination was essentially negative except for an attitude of combined hope and despair that the new insulin would be of help in her case.

Protamine Insulin Record.—August 28 protamine insulin 150 units and regular insulin 50 units were given before breakfast, with a diet of protein 70 Gm., fat 80 Gm., carbohydrate 175 Gm. The twenty-four hour urine specimen showed 16.2 Gm. of dextrose, but glycosuria which was present until before supper disappeared after the evening meal. The blood sugars on this day were: 8 a. m., 62 mg.; 8 p. m., 66 mg. (the 62 mg. fasting blood sugar on this day had been preceded by 30 units of regular insulin administered at 1 a. m.). August 29 the weight was 123 pounds (56 Kg.); protamine insulin 150 units and no regular insulin was given on this date; the twenty-four urine specimen was negative for sugar and the 8 a. m. blood sugar was 57 mg. and the 8 p. m. blood sugar was 58 mg. August 30, protamine insulin was continued at 150 units with no supplemental regular insulin. The twenty-four hour urine specimen showed a trace of sugar and the fasting blood sugar was 46 mg. and the 8 p. m. blood sugar 63 mg. August 31, protamine insulin was maintained at 150 units and the patient continued to be sugar free. The fasting blood sugar on this date was 42 mg. and the weight 126 pounds (57.2 Kg.). She was discharged from the hospital on this date with instructions to continue on the same diet and to reduce protamine insulin by units of 10 to the lowest possible level. During her stay in the hospital a ravenous appetite developed, but increased appetite was the only symptom of hypoglycemia observed or complained of. It is interesting to note that this patient really desired and wanted her meals for the first time in years, and the subjective improvement was amazing. Whereas in the past an "I don't care" attitude had long prevailed, an encouraging "I am now like a normal human being" feeling became apparent. The brief subsequent history in this case is also most interesting. September 10 the patient was taking protamine insulin 120 units and was sugar free twenty-four hours a day and weighed 135 pounds (61 Kg.); she was still enjoying her food and feeling "the best she had ever felt." September 15 an infection of the upper respiratory tract developed and she began to show from 2 to 4 plus glycosuria at all times during the day. She increased protamine insulin to 140 units and maintained it at that level. In spite of severe glycosuria in the presence of an acute infection of the upper respiratory tract, she has shown no urinary evidence of acidosis, nor has she taken any supplemental regular insulin during this period. September 26 she was showing a 2 plus glycosuria at all times during the day and there was evidence of a moderate residual infection in the right antrum and in the right frontal sinus. Whereas in the past an infection of this type invariably produced signs and symptoms of varying degrees of acidosis, there has been no evidence whatever of such a condition being existent during the present illness. It would seem that protamine insulin definitely tends to prevent acidosis in the presence of infection in the patient with severe juvenile diabetes, as this fact has been observed in other cases herein mentioned. The patient's weight, September 26, was 134 pounds, and she stated that she "felt fine."

In this case there was a total gain in weight of 13 pounds (6 Kg.) in spite of a rather persistent infection of the upper respiratory tract. On a 20 per cent caloric increase in her diet there was a diminution in

insulin requirements (under normal conditions) with the prospect of further insulin dosage reduction in the future.

CASE 10.—History.—F. R., a white youth, aged 16, presents the most clinically severe juvenile diabetic record under observation in the Rochester General Hospital. His diabetic history, in brief, is that diabetes was first diagnosed ten years before at the age of 6 years, the onset of the disease being sudden and acute. Since 1926 the patient had had ten admissions to the Rochester General Hospital, one of these admissions being for tonsillectomy in 1934 (tonsillectomy and adenoidectomy being done because of frequent infections of the upper respiratory tract). Early in 1935 there were two admissions for catarrhal jaundice, at which time the complications of this disease plus the acute diabetes made the prognosis very grave, but rather unexpected recovery occurred. The patient has been under insulin since 1927 in dosages varying from 40 units daily in divided doses to in excess of 100 units daily in divided doses. At no time up to the present had it been felt that his diabetes was adequately controlled. Since 1933 the general average of all blood sugars after food varied between 300 and 500 mg., and the patient had never been known to be sugar free in recent years in spite of massive doses of regular insulin. His weight in January 1936 was 95 pounds (43 Kg.). The patient was admitted to the wards of the Rochester General Hospital July 16, 1936, and remained there until July 26. He had been and was continued on a diet of protein 80 Gm., fat 90 Gm., carbohydrate 170 Gm. Regular insulin at the time of hospitalization had been 45-20-45. During the first day in the hospital under his usual routine of regular insulin the fasting blood sugar was 275 mg. and the 8 p. m. blood sugar 450 mg. with no urinary evidence of acidosis. The carbon dioxide combining power and cholesterol were of normal values on the first day at the hospital. Heavy glycosuria was present during all of the first day.

Protamine Insulin Record.—On the second day in the hospital, protamine insulin 75 units and regular insulin 20 units, both given before breakfast, were instituted. The blood sugar values remained high on that day, being taken twice a day, fasting and at 8 p. m. Protamine insulin was gradually raised to 120 units and regular insulin 25 units before the urine became sugar free for twenty-four hours a day. With this dosage, fasting blood sugars varied between 85 and 65 mg., the 8 p. m. blood sugar being 278 mg. On the morning the blood sugar was 65 mg. the patient had a mild insulin reaction, which was promptly relieved by orange juice; and on another morning, with a blood sugar of 85 mg., there were slight symptoms of hypoglycemia. Since his discharge from the hospital, July 26, the patient has been followed at weekly intervals in the diabetic clinic. August 6, under protamine insulin 120 units and regular insulin 30 units, the blood sugar three hours after food was 534 mg., the fasting urine being negative, while the urine three hours after food was 3 plus with negative acetone and diacetic acid reactions. During the weeks of August 13 and 20 there were occasional days with heavy glycosuria, the blood sugar after food on August 13 being 334 mg. August 20, the blood sugar after food was 80 mg. August 27 on the same dosage of protamine insulin and regular insulin the blood sugar two hours after food was 190 mg. The patient stated at this time that he on occasion "spills" sugar after breakfast. September 3 the patient was taking protamine insulin 120 units, regular insulin 35 units and was sugar free twenty-four hours a day. September 10 insulin was as of September 3 and he was sugar free twenty-four hours a day, blood sugar after food being 44 mg. (the patient stated that he had no symptoms of reaction that morning, although on September 6 and 7 he had experienced slight reactions two hours after breakfast). Regular insulin was reduced to 25 units, protamine insulin being maintained at 120 units. September 17 on protamine insulin 120 units and regular insulin 25 units the patient was sugar free twenty-four hours a day. The blood sugar after breakfast this morning was 84 mg. He was now reducing his dosage of regular insulin in an attempt to eliminate it entirely.

The patient, who is reasonably intelligent and very cooperative, stated that he felt "the best he had ever felt." His weight, which was 97 pounds (44 Kg.) at the start of protamine insulin control, was on September 17 104 pounds (47 Kg.). He is in no way inconvenienced by taking 3 cc. of protamine insulin at

one injection, at one site of injection, nor has he ever observed any subcutaneous reaction to this relatively large injection. At the present time he may be considered a perfectly controlled diabetic patient, but it is not felt that the supplemental dosage of regular insulin given twenty minutes before breakfast can be avoided permanently in this case, although at present the protamine insulin dose has been raised to 140 units and the supplemental regular insulin has been abolished, and the patient states that he is sugar free throughout the day; but blood sugar determination and hospital urinalysis remains to be done to determine whether or not regular insulin is essential. He is continuing on a diet of protein 80 Gm., fat 90 Gm., carbohydrate 170 Gm., and states that his appetite is much better than it was under his old regimen.

The patient also had a course of a commercial preparation of the pituitary growth hormone early in 1936, the dosage being 2.5 cc. subcutaneously each week for three months. His height in January 1936 was 61 inches (155 cm.) and in May it was 62 inches (157.5 cm.). The present height is 63½ inches (161 cm.).

COMMENT

Although case 8 is of the type that one likes to report from the standpoint of most successful results, it is significant that all these patients are doing well clinically whether high blood sugars are present or not; such was certainly not the case in some cases prior to the institution of protamine insulin. The obvious convenience of administration of all insulin before breakfast in juvenile diabetes needs no comment. It is felt that many of these patients required much more regular insulin than they had been taking under the old regimen to afford adequate control of their diabetes. The subjective and objective improvement in all cases has been most striking, and all cases have evidenced objective gains as determined by gain in weight and the like. All these cases have taken their total required protamine insulin at one site of injection without signs of local subcutaneous reaction. We intend to investigate further the question of whether or not there is any elevation of the renal threshold in some of these cases that have presented relatively high blood sugar levels without "evidence" of glycosuria. My associates and I considered cases 9 and 10 to be true examples of "insulin wasters," and the efficiency of protamine insulin has been most obvious in these two cases. We also feel that there is definite evidence that protamine insulin apparently prevents diabetic acidosis in juvenile diabetic patients suffering from respiratory infections.

SUMMARY

1. Ten cases of diabetes in juveniles are being satisfactorily controlled with protamine insulin, all insulin being given before breakfast.
2. Marked subjective improvement has been the rule in all cases.
3. Hypoglycemic reactions with protamine insulin, while comparatively rare, may be insidious in onset and very severe.
4. No local subcutaneous reactions have been observed from massive doses of protamine insulin injected at a single site.
5. Protamine insulin seems to prevent diabetic acidosis in infections, although profuse glycosuria may be present.
6. There is some evidence that protamine insulin may tend to raise the renal threshold in certain cases.
7. Protamine insulin is highly efficacious when used in cases of "insulin wasters."

ADDENDUM

The foregoing article, written of October 1936, is now subject to the following brief addition. There have been no reasons to change the basic conclusions

mentioned. Patients 1, 5, 7, 8 and 10 have progressed normally, the tendency being toward diminished protamine insulin requirements (patient 10 now requires but 100 units daily of protamine insulin and no regular insulin). Patient 6 underwent an appendectomy for acute appendicitis in November without need of regular insulin or increase in her regular maintenance dose of protamine insulin and made an uneventful recovery and her insulin requirements have subsequently diminished. Patient 2 developed an acute hysteria in February from which she promptly recovered in the hospital; while she was in the hospital, protamine insulin was discontinued in favor of regular insulin but adequate control of her diabetes had been previously obtained. Patient 3 fell off his bicycle in November, suffering a contusion over one eye, and since this accident his protamine insulin requirements have approximately doubled but he continues to progress satisfactorily. Patient 4 in February developed an acute dementia praecox for which asylum commitment was required. His diabetes, however, has been adequately controlled with protamine insulin.

The question has been raised that protamine insulin might be a precipitating factor in the psychoses of patients 2 and 4, but we do not feel at this time that there is any adequate evidence to support such a contention.

Clinical Notes, Suggestions and New Instruments

A CONSERVATIVE OPERATION FOR THE CURE OF SO-CALLED INGROWN TOENAIL

ROBERT W. BARTLETT, M.D., St. Louis

Recent reports in the literature of large series of cases of ingrown toenail make it apparent that the methods of treatment in common usage yield far too high a rate of recurrence and too long a period of incapacity to the victims of this frequent malady. The thoughtful recent analysis of Keyes¹ is fairly representative of current practice, for in a series of 110 cases treated in several St. Louis institutions the recurrence rate was 13.6 per cent and the average period of healing after standard operative procedures was nineteen days. Also, the period of time until pain was relieved, varying with the method of operation, averaged between two and one-half and seven days.

Operations for the cure of ingrown toenail fall into two main classes: (a) those in which the attack is aimed principally against a strip of nail and the matrix underlying the nail base and (b) those in which the nail wall is made the site of plastic procedures. Of the former the most common procedure involves the excision of a wedge of tissue down to the periosteum of the terminal phalanx to include a strip of nail about one-fourth inch wide, the underlying nail bed and matrix and the adjacent nail wall and ulcer. The Winograd² operation is based on the same principle of removing the nail bearing matrix but is less radical as concerns the soft tissues. Complete removal of the nail without the matrix is to be condemned because the patient is almost certain to have a recurrence when the new nail comes in and complete removal of the nail plus matrix is far too radical, giving too long a period of disability and healing. A clear review of the anatomy about the toenail may be obtained in Maximow's³ recent textbook.

Soft tissue operations as described by Emmert,⁴ Kenerson⁵ and Winslow⁶ consist essentially of removing all the soft parts from the side of the toe in one slice, thus leaving a large raw surface which takes a month or more to heal over. Likewise the procedure set forth by Ney⁷ of cutting two pedicle grafts on the side of the toe and then removing a slice of soft tissue beneath them is quite radical and requires from two to seven weeks for complete healing.

At this point I would suggest that the terms "ingrowing toenail" and "ingrown toenail" are misnomers. This is essentially a disease of civilization and is said to be unknown among the primitive races who do not wear shoes. The etiology in the vast majority of cases seems clearly to be shoes that are too narrow and often too short; these cause the nail wall to be pressed against the sharp nail edge, resulting in a break in the skin with subsequent infection of the soft tissues, ulcer formation, and the heaping up of granulation tissue. I do not subscribe to the belief that the nail actually changes the course of its growth down into the soft tissues.

The high rate of recurrence and long period of disability associated with the standard operations for ingrown toenail are the reasons for the reporting of the following original operative procedure as practiced by Dr. Bartlett Sr. and his associates for many years. The method was commented on by Keyes¹ several years ago. Its basic principle is different from any other known to us in that a wedge of soft tissue is removed from the side of the toe through an uninfected field, with the result that when the skin edges are brought together the nail wall is pulled away from the edge of the nail and held away permanently by the subsequent scar tissue formed. In addition, healing is invariably by first intention in our experience. Needless to say, the patient must be instructed as to properly fitting shoes so that future trouble may be avoided.

When the patient is first seen, the soft tissues are usually acutely inflamed and the toe quite tender. He is then sent home with instruction to soak the foot in hot water several times a day and to rest it as much as possible. When he returns in from four to seven days the infection will be found to have subsided markedly and he may then be operated on without hospitalization.

TECHNIC

The entire toe is prepared with iodine and alcohol or any other suitable solution and draped, after which the digital nerves are blocked with 2 per cent solution of procaine hydrochloride with 2 minims (0.12 cc.) of epinephrine per ounce added. The site of injection selected is just distal to the metatarsal phalangeal joint. From five to ten minutes is required for analgesia to be complete, after which a sterile rubber band tourniquet is supplied at the base of the toe so as to insure a dry operative field. The site of the so-called ingrown toenail is then covered with an alcohol sponge, and a wedge of uninfected tissue is excised from the side of the toe extending from a short distance proximal to the level of the base of the toenail to a point midway between the tip of the toe and the corner of the nail. The wedge extends inward to the depth of the bone, and externally its widest point is at the level of the ingrown nail. At this point the width of the skin excised should be about one-fourth inch. The skin edges are then approximated with five or six interrupted silk stitches and it becomes apparent how well the nail wall has been pulled away from the nail edge. At this point I generally trim off the corner of the nail and then apply a dry dressing, after which the tourniquet is removed. The patient returns home with instructions to rest and elevate his foot for one day, after which he may go about with a slipper or cut out shoe in a fairly normal manner. The dressing is changed on the third day and the stitches are removed at the end of a week. In all our cases there has been primary healing and the patients have experienced little pain or disability after forty-eight hours.

TYPICAL CASE REPORTS

CASE 1.—Miss L. W., aged 20, of Maplewood, Mo., had a typical ingrown toenail of the lateral aspect on the left big toe.

From the Department of Surgery, Washington University School of Medicine.

1. Keyes, E. L.: The Surgical Treatment of Ingrown Toenails, J. A. M. A. 102: 1458-1460 (May 5) 1934.

2. Winograd, A. M.: Modification in Technic of Operation for Ingrown Toenail, J. A. M. A. 92: 229-230 (Jan. 19) 1929.

3. Maximow, A. A.: A Textbook of Histology, Philadelphia, W. B. Saunders Company, 1930, pp. 422-425.

4. Emmert, cited by Dowd, C. N.: Twenty-Nine Cases by Anger's Method, M. Rec. 43: 472, 1893.

5. Kenerson, V.: Operations for Ingrowing Toenail and Hallux Valgus, New York M. J. 82: 682-696, 1905.

6. Winslow, N.: Ingrowing Toenail, Hosp. Bull. Univ. Maryland 10: 99, 1914.

7. Ney, G. C.: An Operation for Ingrowing Toenails, J. A. M. A. 80: 374 (Feb. 10) 1923.

June 8, 1936, she was instructed to have one week of hot soaks preoperatively.

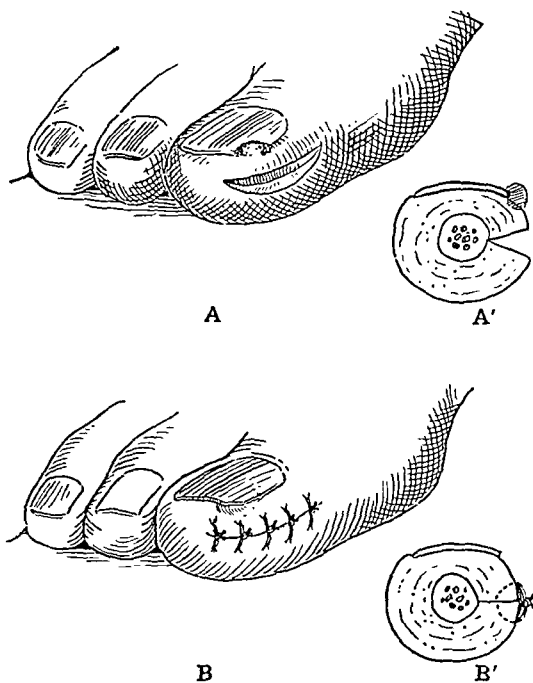

June 15, under digital nerve block anesthesia, a wedge of tissue was excised from the lateral side of the left big toe down to the phalanx. The skin was closed with interrupted silk stitches. A dry dressing was applied.

June 17 there was no evidence of infection of the incision. A dry dressing was applied.

June 22 the stitches were removed. For the past few days the patient had been partially confined to bed with recurrence of hemorrhage from esophageal varices but was off the foot the first day only because of discomfort.

October 21 she reported that she had had no further trouble from the foot. She started wearing regular shoes on the seventh day after the operation. Examination showed that the soft tissues had held away from the lateral border of the nail and that the nail was growing out normally.

CASE 2.—Mrs. M. T., aged 54 of East St. Louis, Ill., seen Oct. 21, 1935, had had trouble with ingrown toenails for many years. These were most marked on the lateral aspect of each big toe, more so on the left than on the right.

A shows a wedge of tissue excised from the side of the toe through an uninfected field. The incisions extend from just proximal to the level of the base of the nail to a point midway between the tip of the toe and the corner of the nail. Externally the widest point of the wedge is opposite the site of the "ingrown toenail." A' shows the apex of the wedge extending to the bone.

B and B' show the nail wall pulled away from the side and corner of the nail; also the corner of the nail trimmed off.

October 28, under digital nerve block anesthesia, a wedge of soft tissue was excised from the lateral aspect of the left big toe down to the phalanx. The skin edges were then approximated with four interrupted silk stitches, thus pulling the soft tissues adjacent to the ingrown toenail away from it. A dry dressing was applied.

October 31 the wound was clean. A dry dressing was applied.

November 4 the incision was clean. The stitches were removed. The patient was off the foot only one day postoperatively and then walked without discomfort.

December 9 she reported that she had continued without discomfort.

Oct. 22, 1936, she reported that she had had no further trouble. Examination showed the soft tissues nicely pulled away from the corner of the nail.

SUMMARY

1. The original operation for the cure of so-called ingrown toenail here presented is a clean procedure, allowing primary

union, and is curative without being radical. The period of postoperative disability and discomfort is far less than with any other method with which I am familiar.

2. I have not seen a single recurrence following this procedure.

3. It is essential that the etiology of this lesion be explained to the patient so that ill fitting shoes may not be worn in the future.

4. The terms "ingrown toenail" and "ingrowing toenail" are misnomers.

929 University Club Building.

HEREDITARY PRANCE-GAIT

EDWARD PARNALL, M.D., ROCHESTER, N. Y.

In the city of Rochester, N. Y., within the parish of Our Lady of Mount Carmel, there lives a family of seven individuals whose affliction has caused them to be called "i cavalli" by the neighbors. The reason for the nickname, which was not given in any unkindly spirit, is a peculiar prancing, high-stepping gait, which characterizes all but two of the seven, in varying degree.

The condition came to my attention through the oldest son, Lorenzo, who came to the orthopedic clinic of the Rochester General Hospital complaining of pain in his right hip, and of nothing else. Physical examination brought to light a paralysis of both anterior tibial muscles, which caused an obvious foot-drop gait. It seemed to the examiner that the patient, in order to balance himself better in walking, held his hips slightly flexed and his spinal column in considerable lordosis. Examination of the painful hip proved negative, nor was any lesion demonstrated by x-ray examination. There was no history of any previous infection with poliomyelitis, and the boy remarked that his father walked with a limp. He was then lost sight of.

At a later date, when I had business in the neighborhood of the family, I learned of its nickname and had an opportunity to observe all its other members.

The father, Angelo, was born in Italy and states that neither his father, mother, uncles nor brothers were affected. He is not sure of his grandfather. He himself is a laborer, able bodied and active. He walks with a moderate prancing gait, showing on examination a total paralysis of both anterior tibial muscles, with no other muscle involved.

The mother, born in Italy, is unaffected.

The oldest child, a woman in her twenties, is unaffected.

The second child, Lorenzo, walks with a very gross prancing gait, lifting his feet high off the ground in order not to drag his toes, with moderate flexion of the hips and considerable lordosis of the lumbar spine, as described. Tibial paralysis was as described.

The third child, an adolescent girl, has the paralysis described, without the postural deformity of her older brother.

The fourth child, a boy of 13, has the paralysis described, slight lumbar lordosis, and is troubled by frequent falling.

The fifth child, a boy of 10 or 12, has the paralysis described, no lordosis, moderate prance-gait, but no complaints.

The cooperation of the father was very hard to secure, my efforts to obtain his consent to a more thorough investigation meeting with flat refusal. The boy Lorenzo, who is now under the care of a chiropractor, was urged to have tendon transplants. However, it was well established that the only muscle to be affected was the tibialis anterior of each leg. The electrical reactions of the affected muscles would have been desirable to obtain, not to mention biopsies in addition. At the present writing, therefore, it is impossible to state whether the condition is due to absence of the muscle or to a peripheral paralysis. It seems to me that the former is the correct hypothesis, as there is no anterior tibial tendon palpable in its proper course. The condition bears no similarity to anything I have ever seen or heard of, except cases of congenital absence of muscles. Muscular dystrophy, myasthenia gravis, dystrophy of Charcot-Marie-Tooth and allied muscular paralyses, including those with a hereditary factor, seem manifestly unlike it. I have made an extensive search through the literature for a report of a similar lesion but so far have been unsuccessful.

One is somewhat at a loss to fit a name to this syndrome. "Hereditary foot-drop," "familial foot-drop" describe only the appearance of the condition, while "hereditary absence of the tibialis anterior muscle" is not a proved certainty. One might take a leaf out of the neighbors' book and call it "cavallosis" or wax platonistic and suggest "pranciness." Until it is possible to do a dissection of the region affected and prove the exact nature of the lesion, I feel that "hereditary prance-gait" is a pathonym both descriptive and practical.

277 Alexander Street.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

NOVATROPINE.—Homotropinemethylbromide.— $C_{16}H_{21}O_2N.CH_2Br$.—The methylbromide of the alkaloid homatropine.

Actions and Uses.—Novatropine is proposed for use in the treatment of gastro-intestinal spasm and hyperchlorhydria. Animal experimentation has shown it to be less active than atropine but also less toxic.

Dosage.—Adults: one or two tablets three times daily before meals; children and infants: according to age.

Manufactured by Campbell Products, Inc., New York. No U. S. patent. U. S. trademark 240,537.

Novatropine Tablets, $\frac{1}{4}$ grain: Each tablet contains $\frac{1}{4}$ grain (2.5 mg.) homotropinemethylbromide.

Novatropine occurs as an odorless, white, crystalline powder, possessing a bitter taste, soluble in water and alcohol but insoluble in ether. It melts between 191 and 192 C., with slight decomposition. Aqueous solutions (1 in 50) are neutral to litmus.

Dissolve about 0.5 Gm. of novatropine in 25 cc. of distilled water; separate portions of 2 cc. are not precipitated by 1 cc. portions of sodium carbonate solution, sodium hydroxide solution, or trinitrophenol solution (distinction from most of the alkaloids of atropine) but are precipitated by 1 cc. portions of potassium mercuric iodide solution, iodine and potassium iodide solution, and a 1.5 per cent solution of silicomolybdic acid. Add a few drops of nitric acid to about 0.05 Gm. of novatropine, evaporate the mixture to dryness on the water bath, cool the residue and add a few drops of alcoholic potassium hydroxide solution: the residue does not become violet colored (distinction from atropine, hyoscyamine and scopolamine).

Add 0.5 cc. of ammonia to 1 cc. of an aqueous solution of novatropine (1 in 100), shake the mixture with chloroform, remove the aqueous layer, and evaporate the chloroform solution to dryness on the water bath. Warm the residue so obtained with about 1.5 cc. of a solution made by dissolving 1 Gm. of mercury bichloride in 50 cc. of a mixture of 5 volumes of alcohol and 3 volumes of distilled water: it does not develop a yellow or red color (distinction from homatropine hydrobromide, atropine and hyoscyamine).

Incinerate about 0.5 Gm. of novatropine, accurately weighed: the ash amounts to not more than 0.1 per cent. Dry about 0.5 Gm. of novatropine to constant weight at 100 C.: the loss in weight does not exceed 0.1 per cent. Transfer about 0.3 Gm. of novatropine, accurately weighed, to a 500 cc. Kjeldahl flask and determine the nitrogen content according to the method described in Methods of Analysis of the Association of Official Agricultural Chemists, fourth edition, page 23, art. 19: the amount of nitrogen is not less than 3.7 per cent, nor more than 3.85 per cent. Transfer about 0.3 Gm. of novatropine, accurately weighed, to a 400 cc. beaker and determine the bromide content according to the method described in Methods of Analysis of the Association of Official Agricultural Chemists, fourth edition, page 131, art. 35: the amount of bromide found corresponds to not less than 21.3 per cent, nor more than 21.9 per cent.

PAPAVERINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1936, p. 321).

Papaverine Hydrochloride-Mallinckrodt.—A brand of papaverine hydrochloride-N. F.

Manufactured by Mallinckrodt Chemical Works, St. Louis.

OPTOCHIN HYDROCHLORIDE.— $C_{16}H_{22}N_2OH.O.C_2H_5.HCl$.—The hydrochloride of ethylhydrocupreine.

Actions and Uses.—See general article, Ethylhydrocupreine, N. N. R., 1936, p. 216.

Dosage.—For application to the eye and instillation into the conjunctival sac, a freshly prepared 1 or 2 per cent solution is used. It is not recommended for oral administration.

For standards see the U. S. Pharmacopeia under Aethylhydrocupreinae Hydrochloridum.

Tablets Optochin Hydrochloride, 0.1 Gm.

Manufactured by Rare Chemicals, Inc., Nepera Park, N. Y., under U. S. patent 1,062,203 (May 20, 1913; expired) by license of the Chemical Foundation, Inc. U. S. trademark 99,822.

Council on Foods

THE COUNCIL ON FOODS HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.
FRANKLIN C. BING, Secretary.

STRAINED FRUITS AND VEGETABLES IN THE FEEDING OF INFANTS

Milk is the principal food for babies, but other foods are desirable or essential. Carbohydrate supplements are customary items of the diet of the bottle-fed infant at an early age. It is usual also to include orange juice or some other food that provides vitamin C, and cod liver oil or other source of vitamin D. Within the last two decades the addition to the infant's diet of a variety of cereal products, toast and zwieback, eggs, fruits and vegetables has been widely adopted by pediatricians.¹ Solid foods when first given to the infant must be finely divided in order that the baby may swallow them and because coarse particles of tough fiber are mechanically irritating to the delicate digestive tract of the very young infant. The preparation of coarser vegetables and fruits by forcing them through a sieve or colander is therefore not only desirable but at the beginning is usually necessary. Directions for preparing sieved foods in the home are relatively simple and, properly prepared, the home strained foods are not inferior in nutritive value to the commercial products. The manufacturers of canned foods have met the demand for strained products by marketing a variety of canned sieved foods. It is the purpose of this report to consider the evidence that is now available and to summarize in the light of present knowledge the nutritional significance of sieved fruits and vegetables.

Among the products that have been submitted to the Council on Foods there now stand accepted a number of brands of sieved foods. These may be divided conveniently into several groups:

1. Vegetables packed singly, including asparagus, beets, carrots, celery, beans (green and wax), peas, spinach and tomatoes.

2. Vegetable combinations or "soups," which are sometimes packed with added cereal or beef broth.

3. Strained fruits packed singly or in combination with other fruits.

4. Products which are related to the foregoing products in that they are intended for the diet of the infant, including cereals, which are sometimes prepared with added wheat germ or milk, and meat products such as beef broth and so-called liver soup which is composed of beef liver, mixed vegetables, whole cereals and beef broth.

The methods of preparing commercial canned sieved foods vary somewhat in different factories. The raw materials are usually fresh fruits and vegetables, but some firms begin with products that are already canned. Briefly outlined, the general canning process consists of heating the food, after preparation for cooking, in a closed kettle under light steam pressure until it is soft enough for sieving. It is then forced through a cylindric monel metal screen with very fine holes, usually 0.02 inch in diameter. Coarse fibers that will not pass through the sieve are discarded and the sieved food is conducted to vacuum tanks, where the water content may be adjusted to secure the desired consistency. The product is packed into cans, sealed and processed according to the requirements of the individual food. It is the aim of most manufacturers to keep the destruction of vitamin C as low as possible; this is aided by performing the operations in a closed system in which air is excluded by means of steam or by high vacuum. Loss of soluble constituents of fruits and vegetables is avoided as far as possible by discarding no liquid during cooking, straining or packing.

Composition.—The composition of individual commercially strained fruits and vegetables is largely dependent on the composition of the original products from which they are made. It is, however, advantageous to consider the average composition of strained foods as a group from the standpoint of the contribution these foods might make to the diet of the baby.

1. Brennemann, Joseph: Breast Feeding and Mixed Feeding, in Brennemann's Pediatrics, Hagerstown, Md., W. F. Prior Company, Inc., 1937, vol. I, chapter 25.

In the accompanying table is shown a summary of the important food values provided by the majority of brands of sieved foods that now stand accepted by the Council.² Figures are also included that represent average values for pasteurized cow's milk, cod liver oil, orange juice, sieved canned tomatoes, whole and refined cereal and egg yolk. These foods, with the possible exception of egg yolk, may be considered as basic in the diet of the normal infant. Carbohydrate supplements are usually given in addition, but for the purpose of the present discussion these may be omitted.

From the table it may be estimated that a 6 or 7 months old baby who is taking among other things 24 ounces of pasteurized cow's milk, 2 teaspoonfuls of cod liver oil, 1 ounce of orange juice, the equivalent of one-half ounce of whole grain cereal (dry) and one egg yolk is receiving from these sources a daily total of approximately 28 Gm. of protein, 0.86 Gm. of calcium, 0.76 Gm. of phosphorus and 3.6 mg. of iron. This infant would also be receiving approximately 7,100 U. S. P. units of vitamin A, 100 International units of vitamin B₁, 375 International units of vitamin C, more than 700 U. S. P. units of vitamin D and more than 400 Sherman-Bourquin units of vitamin G. Although the baby's requirements for these dietary essentials are not known with numerical accuracy, clinical experience indicates that with the possible exception of iron and vitamin B₁ the foregoing quantities of these factors are

titles is receiving ample supplies of vitamins A and C from these sources alone. However, one should not lose sight of the fact that nowadays a considerable number of infants may receive their entire quota of vitamin D from sources which, unlike cod or other fish liver oils, are devoid of vitamin A. For infants who receive no vitamin A other than that supplied by ordinary foods, the canned strained fruits and vegetables may be an important supplementary source of this essential vitamin. Of course not all strained foods are good sources of vitamin A, but carrots, spinach and tomatoes may assay as high as 800 or more U. S. P. units of vitamin A per ounce.

Strained Foods as Sources of Iron.—It has now been more or less generally accepted that the quantities of iron furnished by either breast milk or cow's milk do not adequately meet the requirements of the normal infant. Nature provides for this dietary deficiency by supplying a reserve of iron in the liver and other tissues and in the blood itself of the child before birth.³ This reserve supply might be expected theoretically to last until the child is about 6 months old, but it is usually exhausted considerably before this time. Metabolism studies of young infants usually show a negative iron balance.⁴ A slight degree of anemia appears to be more prevalent among infants considered normal than has been previously recognized. The conclusion has been drawn that the average baby is probably living on a relatively slight margin of safety with respect

Average Food Values of a Few Foods Used in Infant Feeding

Food	Quantity	Calories	Protein, Gm.	Calcium, Gm.	Phos- phorus, Gm.	Iron, Mg.	Vitamin				
							A Units	B ₁ Units	C Units	D Units	G Units
Cow's milk, pasteurized.....	24 fl. oz.	490	23	0.82	0.62	0.42	2,000	70	35-120	...	400
Cod liver oil, minimum stan- dard U. S. P.	1 tsp.	35	2,240	815	...
Orange juice, fresh.....	1 fl. oz.	12	...	0.009	0.005	0.07	27	9	300	...	10
Canned tomatoes, sieved.....	2 fl. oz.	13	...	0.006	0.014	0.24	600	20	200	...	14
Egg yolk.....	1	56	2.5	0.021	0.079	1.3	600	15	...	20 to 100	35
Cereal, whole grain (oatmeal)..	½ oz. dry	55	2.3	0.010	0.056	0.5	15	?
Cereal, refined (farina).....	½ oz. dry	50	1.6	0.003	0.019	0.1	?	?
Canned strained fruits and vegetables											
Minimum.....	2 oz.	12	0.2	0.006	0.006	0.6	400	3	18	...	5
Maximum.....	2 oz.	30	0.8	0.018	0.028	1.8	7,200	24	280	...	23

These figures represent approximate values only. International units are designated except for vitamin G, which is reported in Sherman-Bourquin units.

suitable under normal conditions; there are, of course, variations in the requirements at different ages. With these figures in mind, one may with profit consider the composition of canned sieved foods and the contribution that they may make to the diet.

From the figures presented in the table it can be concluded that the amounts of protein, fat, calories, calcium, phosphorus and vitamin G which might be furnished by 2 ounces of the majority of canned sieved foods are hardly to be considered significant additions to the baby's diet. On the other hand, some of these foods contain appreciable quantities of vitamins A, B₁, and iron, and a few—such as canned tomatoes, canned spinach and other greens—contain appreciable amounts of vitamin C. The strained foods provide also crude fiber, iodine, copper and other substances the nutritional importance of which cannot be evaluated at the present time because of lack of sufficient evidence.

It seems probable, in the light of present-day evidence, that the average normal infant's requirements for vitamin A and vitamin C are adequately met by an intake of approximately 3,000 International units of the former and about 300 International units of the latter vitamin. On this assumption it is obvious that the normal infant who is fed whole milk, cod liver oil and either orange or tomato juice in customary quan-

ties to its intake of iron, and for some babies the iron supplied by ordinary foods is inadequate.⁵

It has been suggested that the optimal iron requirement during the first year of life may be as high as 0.7 mg. per kilogram of body weight or as much as a total of 5 mg. from 3 to 6 months and 10 mg. from 6 to 12 months of age.⁶ If these large amounts of iron are indeed required, it is evident that the quantity of iron supplied by the basic foods enumerated in the foregoing paragraphs is inadequate and that all dietary sources of this mineral are important. As shown in the table, 2 ounces of commercially canned strained foods may provide from 0.6 to 1.8 mg. of iron. Larger servings will of course supply correspondingly larger amounts. Whether the iron of all fruits and vegetables is effectively utilized by the baby is not clear at the present time. Contradictory results have been reported⁷ and further evidence is necessary. The fact remains, however, that canned strained fruits and vegetables may supply what appear to be significant amounts of this essential dietary factor.

Strained Foods as Sources of Vitamin B₁.—That the quantities of vitamin B₁ supplied by vegetables might be important in infant feeding was suggested by the observations of Daniels, Byfield and Loughlin.⁸ These workers reported that 100 cc. of vegetable soup prepared from comminuted carrots, turnips and celery, and added to the milk feeding of a normal baby at the age of 4½ months, resulted in a marked stimulation of growth. The effects were comparable to those observed following the administration of an alcoholic extract of wheat embryo or an alcoholic extract of a similar vegetable mixture. The authors concluded therefore that increased growth was due to the vitamin B₁ content present in the alcoholic extract of the products investigated. Later Hoobler and other workers found that many infants apparently require more of the antineuritic factor than is ordinarily furnished by milk.⁹ They thought that an additional source of vitamin B₁ should be provided. If it is true that the vitamin B₁ intake of the normal infant under usual conditions is not far above the requirements of the infant, it may well be that the B₁ furnished by a number of commercially sieved foods would be significant in the nutrition of the infant.

Digestibility.—There is ample clinical evidence that commercially sieved foods are well tolerated by the average baby and that digestive upsets caused by these foods are rare. When vegetables are first given to the baby the digestive tract must gradually become accustomed to taking care of this type of food. During such transition periods rather large amounts of the vegetable food usually appear in the stools. The presence of such undigested material in an otherwise normal stool should not cause any fear that the baby is unable to tolerate these foods. Normal infants are able to digest sieved foods after the first few months of life. A factor that is favorable to the ease of digestion of commercially sieved foods is the fine state of division obtained with factory sieves having extremely small perforations. It is for this reason that strained foods also have an important place in certain therapeutic diets, particularly when these diets must be continued over long periods of time. Under such circumstances the commercially sieved foods, particularly vegetables and fruits, offer a considerable convenience to the consumer and may contribute important amounts of iron and of vitamins A, B₁ and possibly other factors to the diet.

Psychologic Importance of Variety in the Diet of the Infant.—An important reason for introducing a variety of foods during the first year of life is the favorable effect on the food habits of the child. As all mothers and pediatricians know, babies readily form habits with respect to foods that, once formed, are not easily broken. For this reason it has been considered important to introduce a variety of flavors and textures and to accustom the child to taking food from a spoon at as early an age as is possible. It has been reported regarding a group of 231 Boston infants that those children fed "solid foods" during the second and third months had better food habits and fewer food dislikes than others in whom such feeding was postponed until the seventh month.¹⁰

There are, of course, many pediatricians who undoubtedly would not be in favor of incorporating strained foods at as early an age as the second or third month. The introduction of strained foods in the baby's diet usually takes place at about the fifth or sixth month, although some pediatricians prefer to wait until later and others introduce some of these foods much earlier. It is important that foods be finely divided when first included in the diet of the infant, but psychologically it is equally important that babies become accustomed to foods of increasing coarseness as soon as they are physiologically able to do so.¹ There are many babies who are mistakenly fed strained fruits and vegetables throughout the period of infancy and even beyond. With such babies it is a common experience that they can be induced to eat coarser foods only with the greatest of difficulty when this is attempted later. It has been

reported that this difficulty may last for years in the home, although it is more readily overcome in the hospital or the nursery school where the child can be taught by example of other children, without the presence of its mother. For these reasons the physician and the discerning mother should not lose sight of the fact that it is important to replace strained foods by coarser foods usually around the sixth to the eighth month, at which time it is psychologically easy to effect the change.

Summary and Allowable Claims for Strained Fruits and Vegetables.—From the evidence that has been reviewed, the Council is of the opinion that strained fruits and vegetables, because of their physical structure, are useful foods for infant feeding and for certain types of therapeutic diets. These strained foods are probably significant as sources of vitamin B₁, iron and possibly other factors. They also contain vitamins A and C in amounts that under some conditions might be important; but, of course, some foods are better sources of these factors than others. There is also a psychologic aspect to the use of strained foods that is important. The baby at an early age should be taught to receive food from the spoon and to accept a variety of flavors and textures. The feeding of strained fruits and vegetables, properly selected to meet the needs of the individual infant at an age of about 4 to 6 months, is generally favored by pediatricians. The Council, of course, believes it to be a question for the physician to decide at what age a baby shall be fed strained foods and at what age it is considered desirable to replace such products with coarser foods.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

FRANKLIN C. BING, Secretary.

FORT WESTERN BRAND HAWAIIAN PINEAPPLE JUICE

Distributor.—Holmes-Swift Company, Augusta, Maine.

Packer.—Hawaiian Pineapple Company, San Francisco.

Description.—Canned unsweetened pineapple juice, the same as Dole Hawaiian Finest Quality Pineapple Juice (Unsweetened) (THE JOURNAL, June 3, 1933, p. 1769).

DAIRY MAID DOUBLE ACTION BAKING POWDER

Distributor.—Dairy Maid Division of Snow King Baking Powder Company, Cincinnati.

Description.—Baking powder, consisting of starch, sodium bicarbonate, sodium aluminum sulfate and calcium acid phosphate. The same as Snow King Double Action Baking Powder (THE JOURNAL, Oct. 13, 1934, p. 1151).

GEM BRAND OLEOMARGARINE

Manufacturer.—Swift and Company, Chicago.

Description.—Margarine prepared from coconut oil, skim milk, hydrogenated coconut oil, cottonseed oil or peanut oil, salt, and benzoate of soda 0.1%.

Manufacture, Analysis, Calories.—Same as Allsweet Brand Oleomargarine (THE JOURNAL, March 21, 1936, p. 1009).

NATION WIDE BRAND WHEAT CEREAL

Distributor.—Nation Wide Stores Company, Brockton, Mass.; St. Louis; Toledo, Ohio; Washington, D. C.; Warren, Pa., and Atlanta, Ga.

Packer.—Campbell Cereal Company, Minneapolis.

Description.—Wheat middlings, endosperm or farina, the same as Blue Ribbon Brand Wheat Cereal (THE JOURNAL, Sept. 21, 1935, p. 967).

AMERICAN FOUNDATION STUDIES IN GOVERNMENT

In the organization section in this issue of THE JOURNAL appears an analysis of the report of the American Foundation Studies in Government on the subject of medical care. Ten thousand physicians who have been more than twenty years in practice and a number of more recent graduates were asked to present their views. Some 2,200 physicians answered and many wrote additional contributions, so that the compilers of the report considered some 5,000 letters in obtaining their cross section of medical opinion as to the status of medical care. The report is therefore a collection of the views of medical men, compiled under various headings, edited with a view to presenting all points of view as clearly as possible, supplemented with some interpretation and analysis by the editors. The report is worthy of careful and critical study. The American Foundation offers its review of the problems of medical care as seen by the physician without drawing any definite conclusions, yet certain indications seem to evolve logically and to these the medical profession may well continue to give serious consideration.

If there is one factor that comes out more obviously from this report than any other, it is the unlikelihood that sickness insurance, either voluntary or compulsory, will answer the problem of medical care suitably for the people of the United States. As Miss Esther Everett Lape,¹ director of the studies, herself stated in a recent issue of the *Atlantic Monthly*, "The medical man believes that compulsory insurance—with its stress upon more care in illness (as opposed to stress upon positive health), with its mass therapy, its regimentation both of doctors on the panel and of patients (in spite of devices to save the principle of the personal relation)—subtly and continuously lowers the quality of medical care, the quality of the medical man, the quality of the patient's conception of health." THE JOURNAL repeats that the outlook would seem to be best for a gradual improvement in medical care by the evolution that has been

going on for some time. The extension of preventive medicine, increased funds for preventive medicine and the improvement of medical knowledge are bound to affect the extent, the severity and the character of illness in coming years. Any fixed plan that failed to take the certainty of these advances into account would involve organization and expenditure far beyond the actual needs of the future. Government machinery once set up is hard to stop; it has the characteristics of the poisonous mushroom, growing profusely and destroying those who feed upon it.

The American Foundation report suggests a further expansion in present provisions for giving a better quality of medical service to more people by the extension of the facilities of tax-supported laboratories so as to make available to physicians generally and thereby to furnish to patients at a low cost many of the modern methods which constitute the difference between knowing and guessing in diagnosis. More and more hospitals are being equipped with competent clinical laboratory service, roentgenologic departments, physical therapy departments and serologic units. These methods are expensive and cannot be utilized to the fullest for all the patients who might benefit by their utilization without more permanent and more adequate financial support either to the hospitals directly or to the patients who require the services. Moreover, many states now provide, through their departments of health, laboratory services which may be utilized by the general practitioner for needy patients. Extension of such services should be of great benefit to the public health and should raise the general quality of medical care when a sufficient number of trained personnel becomes available.

As was revealed again in our recently published survey of hospitalization in the United States, the proprietary hospitals are fast disappearing. The nonprofit voluntary hospitals have been having great difficulty in many places to keep their heads above the quicksands of bankruptcy. High taxes, government regulation, and other political and economic changes have lessened greatly the philanthropic funds available for medical institutions. Periods of depression have kept vacant the rooms and the beds from which hospitals in the past derived excess income for the support of service to the indigent and the new group, of which the social service worker speaks glibly as the "medically indigent." THE JOURNAL would point out again that our hospitals are confronted today with problems much like those confronting the hospitals of Great Britain. The incomes of British hospitals have been diminished by these factors and, in addition, by the application of the compulsory sickness insurance system. The answer for this question, as suggested in Great Britain, may be government aid for the hospitals in relation to the amount of service rendered to those unable to pay for it. At the same time these institutions must retain sufficient independence to permit growth and expansion

1. Lape, Esther Everett: The Health of the Nation, *Atlantic Monthly* 159: 463 (April) 1937.

rather than reversion to the sluggishness that seems invariably to affect institutions under complete and permanent state control. Group hospitalization plans, so intensively agitated in this country by the Rosenwald Foundation and more recently by the American Hospital Association, are today actually nothing but an interesting experiment affecting a small part of the population, if not merely a "stop-gap" for the present critical situation in hospital finance.

The 1,500 page report of the American Foundation Studies in Government concludes with a chapter devoted to limited state medicine and private practice as representing the gradual evolution that is taking place in this country. As was pointed out some years ago by Dr. Thomas Parran,² Surgeon General of the United States Public Health Service, in an article published in *THE JOURNAL*, many of the functions of medical care in many states are already largely under the control of the state. The amount of state medicine varies from a few per cent in some states to 25 or 35 per cent in others. As syphilis, cancer and pneumonia begin to be recognized as public health problems, and as heart disease trembles on the brink of such recognition, we approach even more closely to a recognition that the state is occupying an increasing position of importance in medical care. With workmen's compensation laws, industrial medicine and the various forms of group practice and contract practice invading significant portions of the medical field, organized medical practice also makes tremendous inroads into private medical care. The evolution must be controlled by the medical profession.

No system of medical practice can succeed without the cooperation of the medical profession. Recognizing this fact, the American Foundation report leads to the suggestion for a secretary of health in the President's cabinet as a necessary coordinating authority. The Board of Trustees of the American Medical Association has emphasized its view that a health department subservient to a welfare agency set up for the distribution of funds to the indigent and to find work for the unemployed would be an inadequate recognition for the real place which health should occupy in any government. From ancient Greeks and Romans, through the statesmen of the middle ages, down to modern times, the greatest leaders have stated that the care of the public health should be the first interest of the state. Can it be that American statesmen of today fail to appreciate the essential truth of this governmental aphorism, evolved from thousands of years of human experience? The mere fact that the present budget of our government for preventive medicine and public health cannot compare favorably with the amount of money spent on the dole has been offered as one reason for keeping public health in a subservient position. Perhaps the proportions that now exist may some day be reversed

—a time may come when the nation will spend \$4,000,000,000 a year on preventive medicine and \$100,000,000 on unemployment and the dole. It will no doubt then be a far happier nation.

Fundamental to every consideration of medical service is knowledge of its present adequacy and availability. Doctors who are in intimate contact with the problem probably realize better than any one else how much adequate medical care is actually available. Both terms are difficult to define. If adequate medical care includes a periodic physical examination twice each year, even doctors do not get it—or want it—now. If adequacy involves the attendance of a physician for every vague ache or pain or every rise of a half degree of temperature, the vast majority of our people do not, and probably never will, receive adequate medical care. They do not need that kind of medical care.

If adequacy is the same for New Mexico, South Dakota and Mississippi as for New York City and Chicago, the differences are apparent. But is there likely ever to be equalization? A letter from a country practitioner in Kentucky reveals that in some sections of that state the people do not seem to be especially interested in getting a better quality of medical care than they now have. Yet the social service worker considers them benighted and hints that they are moronic. Is it the duty of the state to give them perfect medical care and make them like it? Adequate medical care cannot be standardized for distribution until many other fundamental needs of our people are satisfied.

The question of adequacy and availability of medical service is closely correlated with the determination of indigence and "medical indigence." The medical profession for many years has prided itself on the fact that it gives of its services freely to all who require them without question when the inability of the individual to pay is apparent. Then depression threw such a burden on some members of the medical profession that they themselves approximated the indigent class. With the advancement of medical science and the increasing cost of giving to all the people the most that medicine can offer, the borders of indigence have been extended upward to create a new class called "medically indigent." In addition there is the group that wants to pay at least a part of the costs of medical service. Physicians cannot wave aside all consideration of money in relationship to medical service. These questions intimately affect the quality of service that can be rendered. The amount of service that has been given to the people in recent years by the medical profession and by the medical facilities of this country runs into many millions of dollars. An increasing burden has fallen on the upper middle class because the exceedingly rich tend to become fewer and fewer. The problem of balancing the medical budget of the future is going to be as difficult as the balancing of the budgets of the nations.

The well informed medical readers of this report will observe that some physicians noted for their opposition

2. Parran, Thomas: Public Medical Care in New York State, *J. A. M. A.* 101: 342 (July 29) 1933.

to the policies of organized medicine express views in their letters to the American Foundation which they have perhaps, because of modesty or reticence, concealed during the agitations of recent years. If one studies carefully the list of those who contributed to the report, it becomes evident that members of medical school faculties, health department officials and specialists dominate the picture. They write on state medicine, insurance, public laboratories and group practice, subjects which most concern the general practitioner. This dominance is perhaps responsible for the impression, which seems to evolve quite naturally from the report, that the future of medicine lies in the medical schools and that many of our present evils would be corrected if the medical schools could be given supervision over standardization of hospitals, control over organized medical practice, and in general management of medical education and the distribution of medical service. The medical schools find themselves at the present time in a difficult situation. There are increasing demands for higher standards; contributions and endowments are lessened; enforced diminution is likely in the amounts of students' fees. It has taken almost a quarter of a century of strenuous effort on the part of organized medicine to raise the standard of medical education in this country. It has had constantly to battle political, personal and proprietary interests in medical schools themselves. It should be obvious that the schools cannot be relied on to raise and to maintain suitable standards in medical education. The utter inability of medical schools in universities that have departments administering medical service to control even the standards of such service in their own schools is an indication of how futile it would be to depend on the medical schools to develop and maintain distribution of medical service for all the people in the future.

If any single appellation is to be given to this report, it is "thought provoking." The reader must be impressed by the obvious earnestness, sincerity and desire to aid of the great majority of those who wrote the letters. These actual records of personal experience compare most favorably with previous compilations of inspired statistics collected by the economists and social service workers who had preconceived opinions and predigested notions as to what ought to be done with medical practice. This report did not set out to prove that compulsory sickness insurance would solve the medical problem. Neither did it set out to prove that doctors alone could solve all our problems. It was designed to present an adequate picture of the American medical scene with the apparent realization that diagnosis must precede prognosis and treatment. Its most important conclusion is that "planning" and not "a plan" is the answer. Leaders of medical thought and opinion know that intelligent planning will maintain and conserve the real values inherent in good medical practice.

SALIVARY IMMUNITY

The recent European epidemic of malignant diphtheria¹ ("diphtheria gravis"), a specific infection refractory to even massive doses of diphtheria antitoxin, has turned the attention of German bacteriologists to the present lack of knowledge of the local non-serologic buccal defenses against this disease. Contrary to conventional theories of immunity, Hermann Dold² of Tübingen found that normal human saliva contains enzymic factors that will not only inhibit the multiplication of diphtheria bacilli in vitro but often kill these micro-organisms within a few hours. Virulent diphtheria bacilli not killed by contact with this normal salivary antiseptic are almost invariably transformed into avirulent types. Weigmann and Koehn³ found that these transformed "mutants" will breed true as apparently true pseudodiphtheria bacilli for at least ten transplants in ordinary culture mediums.

The presence of these "inhibins," or "bacteria-transforming enzymes," in normal saliva has been confirmed by a study of salivary inhibitions and transformations of numerous other bacterial species. Wehrse⁴ for example found that, in the presence of normal human saliva, hemolytic streptococci are often killed in from five to six hours and, if not killed, are almost invariably transformed into nonhemolytic variants. Pesch and Damm⁵ report a similar bactericidal and transforming action on type I and II pneumococci. While the carbohydrate capsule is not demonstrably altered in specificity by the action of normal saliva, mouse virulence is almost completely destroyed.

The "inhibins" in normal saliva are more or less completely removed by Seitz filtration; are nondiffusible through animal membrane and are destroyed quantitatively by heating saliva to 56 C. for thirty minutes. Dold, Lächele and Hsing,⁶ however, have published evidence that the "inhibins" are not identical with the lysozymes of Fleming. Whether or not these "inhibins" are salivary enzymes, epithelial products or antagonistic factors formed or secreted by normal buccal saprophytes has not yet been determined.

The effects of surgical antiseptics, mouth washes and smoking on this natural salivary immunity have not yet been studied. Whether or not the normal salivary bacteriostat is altered quantitatively or qualitatively as a result of bodily chilling is a problem of pressing clinical interest. In this connection, Ignatius⁷ was able to demonstrate presumably identical "inhibins" in normal nasal secretions. This normal nasal bacteriostat

was absent from the nasal discharges of patients suffering from common colds. The possible effect of this normal upper respiratory "inhibin" on filtrable viruses *in vitro* has not yet been studied.

EFFECT OF GONADOTROPIC SUBSTANCE AND ESTROGENS ON BLOOD CALCIUM

In recent investigations on the function of the anterior pituitary, extracts have been obtained that cause histologic changes in the parathyroids and a rise in blood calcium, in addition to other effects. This has been adduced as evidence for the existence of a special parathyrotropic principle.¹ Conclusive proof of the existence of such a substance has been lacking, however, owing to the many difficulties inherent in this type of research; extracts of the pituitary containing single principles have not yet been obtained and the changes observed may be secondary to effects on organs other than the parathyroids.

Important information on this point has now been supplied by recent experiments of Riddle and Dotti² on the effects of a number of endocrine principles on the blood calcium; the observations of these workers appear to have far reaching implications. Anterior pituitary extracts containing follicle-stimulating and thyrotropic principles were found to increase the blood calcium in pigeons. Gonadotropic substance alone from mare's serum also produced this effect; the latter was prevented by castration but not by hypophysectomy or thyroidectomy. The effect was obtained more readily in females than in males. Hypophyseal extracts containing the lactogenic or growth factors but little or no gonad-stimulating substance did not raise the calcium content of the blood. Because of the evidence indicating that the observed effect was mediated through the gonads, Riddle and Dotti then investigated estrogens, androgens and progesterone.

Large doses of two commercial estrogenic preparations said to contain theelin were found to increase the serum calcium. Dihydrotheelin benzoate (estradiol benzoate) had this action to a less degree; dihydrotheelin and theelin were next in effectiveness. Large doses of progesterone had only a slight calcium-raising effect. Three androgens, androstenediol, testosterone and testosterone oxime, did not have this property. These substances were tested on pigeons, rats and dogs, male and female; some were normal, others hypophysectomized or castrate, still others both hypophysectomized and gonadectomized or thyroidectomized and castrate. The blood calcium raising effect was noted in all when estrogen was administered in sufficient dosage for a sufficiently long time.

Whether or not the parathyroid plays a part in this response has not yet been determined; nevertheless, the

work of the Cold Spring Harbor investigators indicates that much more satisfactory evidence than has been provided so far will be necessary before the existence of a pituitary parathyrotropic principle can be accepted. This illustrates anew the complexity of glandular interrelations and exemplifies the difficulties of endocrine research. It is important to emphasize that the significance of these observations with regard to the clinical application of gonadotropic and estrogenic products that raise the blood calcium remains to be determined.

Current Comment

TAX RETURNS UNDER THE SOCIAL SECURITY ACT OVERDUE

The Bureau of Internal Revenue calls attention to the failure of many employers who have less than eight employees in their service to file the tax returns for the month of January required by the federal Social Security Act. Monthly returns must be filed by every employer who has one or more employees in his service, other than domestic servants in his private home or agricultural labor, except certain institutions and organizations that are specifically exempted by the act. Physicians who are employers in default should take prompt action to make the required returns. Hospitals, other than charitable hospitals, must make the same returns as other employers, and a hospital that claims exemption as a charitable hospital must apply to the local collector of internal revenue for official classification as a tax-exempt institution. State, county and other medical associations that are employers of one or more employees are liable for this tax, unless they are organized and operated exclusively for charitable, scientific, literary or educational purposes and no part of their net earnings inures to the benefit of any private shareholder or individual. Such an association, if claiming exemption, must obtain through the local collector of internal revenue verification by the Commissioner of Internal Revenue of its tax-exempt status. Although the tax return for January is past due, the Commissioner of Internal Revenue will not penalize those taxpayers who make their returns without further delay and show reasonable cause for failing to file them within the time allowed by law; however, the delinquent taxpayer must attach to his January return an affidavit setting forth the reasons for his delinquency. Without a just excuse and if a return is not more than thirty days late, a penalty accrues equal to 5 per cent of the taxes due at the time of the return. For each additional thirty days or fraction thereof that the taxpayer is delinquent, an additional 5 per cent penalty accrues, with a maximum penalty of 25 per cent of the taxes. These penalties are in addition to interest on the unpaid tax at the rate of 6 per cent a year. They are independent of the penalties provided for employers or employees who attempt to evade or defeat the collection of taxes or who wilfully fail to perform the duties imposed on them by the law. Returns for February were due on or before March 31. A similar return for each subsequent month is due on or before the last day of the month following that on which it is made.

1. The literature has been reviewed by Collip, J. B.: Chapter VII of *Glandular Physiology and Therapy*, Chicago, American Medical Association, 1935.

2. Riddle, Oscar, and Dotti, L. B.: Blood Calcium in Relation to Anterior Pituitary and Sex Hormones, *Science* 84: 557 (Dec. 18) 1936.

Form SS-1 for the return will be supplied by the local collector of internal revenue on request. The return, together with the taxes due, must be sent to the collector of internal revenue of the district in which the employer's principal place of business is located. It should not be sent to the Bureau of Internal Revenue in Washington or to any officer of the Social Security Board. Employers who have not filed the employer's application for identification number should do so when filing their first returns. Form SS-4 for that purpose may be obtained from any post office or from the office of the local collector of internal revenue.

MACFADDEN SAYS "I TOLD YOU SO" ABOUT SYPHILIS

Bernarr Macfadden says "I told you so" in an editorial in *Liberty* for April 7. The big shot of the big muscle boys claims that the United States Public Health Service, the medical profession, and public health agencies in general are not doing anything new when they promote a drive against syphilis. "Way back when," he printed an article on this subject by Senator Royal S. Copeland in *Physical Culture*. In his present editorial in *Liberty* he repeats some of the fallacies he exploited so boldly in the good old days. In the treatment of syphilis, he recommends fasting two weeks on water alone followed by "a full raw milk diet." So while *Coronet* says that milk causes cancer, "body love" Bernarr uses raw milk for syphilis. It seems this cleanses the blood stream. Toward the end of his editorial the pompadoured physical culturist writes: "The more complicated scientific measures adopted by many physicians may be an improvement over these simple measures but no progressive up-to-date physician who has tested them will deny their value." That lets us all out! But then no up-to-date progressive physician would even think of Mr. Macfadden and scientific medicine in the same set of thoughts.

MULLEIN WEEDS AND BALD HEADS

Early in March, George Jean Nathan, a dramatic critic, no longer young but widely known in a previous generation for the acerbity of his wit, his comely appearance and his association with Mr. H. L. Mencken, indicated that he had relieved himself of baldness by the application to his scalp of tincture of mullein. As a result, both Mr. Nathan and *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* have been deluged with inquiries as to the exact value of this product. Mullein is a common weed. Both the leaves and the flowers have been used since time immemorial as home remedies. An infusion of the flowers was at one time recommended as a home remedy for inflammations of the upper respiratory tract. In Germany the oil of mullein has been used for inflammation of the mucous membranes and also for hemorrhoids. Today mullein is generally recognized by scientific pharmacists as a little used and unessential drug, largely inert, and of little real value except as a demulcent and emollient. With Mr. Nathan it is always hard to know when he is in earnest. From his previous reputation for truth and veracity as well as sagacity, it seems doubtful that he recommended mullein as a hair tonic except with his tongue in his cheek.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

State Medical Meeting at Birmingham, April 20-22.—The Medical Association of Alabama will hold its annual meeting at the Tutwiler Hotel, Birmingham, under the presidency of Dr. Lloyd Noland, Fairfield, and with the Jefferson County Medical Society acting as host. Among others, the following will be on the program:

- Drs. Lee F. Turlington and Clifford Lamar, Birmingham, Contraception, Its Need, Purpose and Accomplishment.
- Dr. Melson Barfield-Carter, Birmingham, Paget's Disease.
- Dr. John Day Peake, Mobile, Report of 189 Cases of Carcinoma of the Cervix.
- Dr. Ernest Vernon Stabler, Greenville, Clinical Importance of Simple Cysts of the Ovaries.
- Dr. Grosbeck F. Walsh, Fairfield, Psychogenic Factors in Disease.
- Dr. Seale Harris Jr., Birmingham, Cardiovascular Syphilis.
- Dr. Hugh Dent Johnson, Montgomery, Presacral Sympathectomy in Dysmenorrhea.
- Dr. H. Earle Conwell, Birmingham, Emergency Traction for Safe Transportation in Fractures of the Long Bones.
- Dr. W. Groce Harrison Jr., Birmingham, The Mechanism of Congestive Heart Failure.
- Dr. Clarence R. Bennett, Eufaula, Angina Pectoris.
- Dr. David B. Snelling, Montgomery, Protamine Insulin in the Treatment of Diabetes Mellitus.
- Dr. James B. McLester, Birmingham, The Functional Patient.
- Dr. James O. Morgan, Gadsden, Mucocoele of the Appendix.
- Dr. Porter P. Vinson, Richmond, The Bronchoscopic Management of Pulmonary Abscess.
- Dr. Hamilton W. McKay, Charlotte, N. C., Certain Phases of Pediatric Urology.

Dr. Frank H. Lahey, Boston, will deliver the Jerome Cochran Lecture Wednesday morning on "Carcinoma of the Colon and Rectum." A public meeting Wednesday evening will be addressed by Drs. Charles Gordon Heyd, New York, President, American Medical Association, on "The Contribution of the American Medical Association to the Public Health" and Edgar W. Norris Jr., Hot Springs National Park, Ark., on "Syphilis." At a meeting of the Birmingham Eye, Ear, Nose and Throat Club, April 20, Dr. James B. Costen, St. Louis, will discuss "Diagnosis of Neuralgia and Ear Symptoms Associated with Dysfunction of the Mandibular Joint."

ARIZONA

Joint Public Health Meeting.—The Arizona and New Mexico public health associations will hold a joint meeting in Phoenix, April 12, prior to the annual session of the Western Branch of the American Public Health Association, April 13-15.

Tuberculosis Association.—Dr. Fred G. Holmes, Phoenix, was chosen president of the Arizona Anti-Tuberculosis Association at its annual meeting in March, at which meeting a report was presented on the tuberculosis program among high school students in Phoenix. It is expected that the program will be continued until June.

CALIFORNIA

Bureau of Venereal Diseases.—Dr. Malcolm H. Merrill, in charge of the syphilis clinic, University of California Hospital, San Francisco, has been made chief of the bureau of venereal diseases of the state department of public health. The bureau was recently reestablished with funds made available through the social security act. It was founded in 1917 but had been discontinued in 1920 on account of lack of funds. Under the new set-up the bureau will carry out the state's program in the national campaign against venereal disease.

Lectures on Medical History.—The University of California Medical School is presenting a series of lectures on the medical history of California. The first discussion, March 25, by Dr. Henry Harris, Berkeley, dealt with the selection of the site of the medical school. Other lecturers in the series include:

- Dr. Edgar L. Gilcreest, San Francisco, March 31, Dr. H. H. Toland and His Work.
- Dr. Robert T. Legge, Berkeley, April 7, Life and Career of Dr. Robert McLean.
- Dr. Wallace I. Terry, San Francisco, April 14, Dr. T. W. Huntington.
- Chauncey D. Leake, Ph.D., San Francisco, April 21, Dr. James Black.
- Dr. Herbert C. Moffitt, San Francisco, April 28, Dr. William Watt Kerr.

CONNECTICUT

Medical Information Bureau.—The Hartford Medical Society and the Hartford County Medical Association are planning to establish a medical information bureau, according to the *New England Journal of Medicine*, to supply to the public adequate and correct information on medical matters through the press and radio. Five members from the city organization and four from the county society, whose services will be entirely voluntary, will manage the bureau. It will be patterned after that of the New York Academy of Medicine.

FLORIDA

Committee on Venereal Disease Control.—A committee on venereal disease control has recently been appointed to represent the Florida Medical Association. Members are Drs. Elijah T. Sellers, Jacksonville, chairman; Joe I. Turberville, Century; Robert D. Ferguson, Ocala; Alvin L. Mills, St. Petersburg; Louis M. Orr Jr., Orlando, and Roy J. Holmes, Miami.

Spring Meeting.—The Florida Midland Medical Society will hold its spring meeting at the Dixie Grande Hotel, Bradenton, April 29, with the following speakers, among others:

Dr. John T. Moore, Tampa, Differential Diagnosis of Acute Abdominal Conditions.

Dr. Howard V. Weems, Sebring, Results of Elliott Treatment in Thirty-Three Cases.

Dr. Rosalie Slaughter Morton, Winter Park, Modern Medicine in Ancient Iran.

Dr. Louis B. Mount, St. Petersburg, Diagnosis of Some Common Contagious Diseases of the Skin.

Dr. Benjamin F. Hart, Winter Park, Low Cesarean Section.

Dr. Joseph Halton, Sarasota, Tumors of the Lung.

Dr. William D. Sugg, Bradenton, The Unusually Placed Appendix.

Dr. Duncan T. McEwan, Orlando, Infectious Abortions: Pathology and Treatment.

Dr. Gideon Timberlake, St. Petersburg, Diseases of the Prostate.

Dr. Fred H. Albee, Venice, will address the dinner session in the evening on "Reconstructive Surgery."

IDAHO

Personal.—Andrew Warner, D.D., Twin Falls, has been placed in charge of the administration of the Idaho State Mental Hospital at Blackfoot. Dr. Charles R. Lowe will continue in charge of the medical and surgical work at the hospital, it is reported.

Society News.—Dr. Paul W. Johnson, Lewiston, addressed the North Idaho Medical Society at a meeting in Lewiston, recently; his paper was entitled "X-Ray Examination of the Gallbladder." Dr. Willard O. Clark, Lewiston, was elected president to succeed Dr. Paul G. Haury, Lewiston; Dr. Albert B. Pappenhagen, Orofino, vice president, and Dr. Joseph E. Baldeck, Genesee, secretary.

ILLINOIS

Society News.—Chauncey D. Leake, Ph.D., professor of pharmacology, University of California Medical School, discussed "Central Nervous System Depressant Drugs" before the Sangamon County Medical Society, Springfield, April 1. —The Peoria City Medical Society will be addressed April 20 in Peoria by Drs. Robert E. Plunkett, Troy, N. Y., general superintendent of tuberculosis hospitals, New York State Department of Health, on "The Role of the Family Physician in the Control of Tuberculosis" and Maxim Pollak, "Results of Tuberculosis Control in Peoria." —Dr. James H. Hutton, Chicago, addressed the St. Clair County Medical Society, East St. Louis, March 4, on "Endocrine Disorders."

Chicago

Lecture Postponed.—The first lecture under the Elizabeth McCormick Child Research Grant, which was to have been delivered April 16 by Dr. Alfred H. Washburn, director of the Child Research Council of the University of Colorado, Denver, has been postponed. This is a new grant not to exceed \$1,000 to be given annually to the Institute of Medicine of Chicago by the Elizabeth McCormick Memorial Fund.

University News.—Plans are under way to establish a medical historical museum at Loyola University School of Medicine. A portrait of the late William C. Austin, Ph.D., professor and head of the department of physiologic chemistry at the school, has been presented to the school's library. —An evening course in physical therapy began at Northwestern University Medical School, April 5, and will continue until June 15. Further information may be obtained from Dr. John S. Coulter at Northwestern.

Dr. Carlson Lectures on Endocrines.—Dr. Anton J. Carlson, professor and head of the department of physiology, School of Medicine, Division of Biological Sciences, University

of Chicago, discussed the control of the endocrine glands at Loyola University School of Medicine, April 2. The lecture was the ninth of an annual series established in 1929 by Alpha Omega chapter of Phi Beta Pi medical fraternity in memory of the late Dr. Samuel A. Matthews, who was professor and head of the department of physiology, pharmacology and therapeutics at Loyola.

IOWA

Society News.—Dr. William F. Snow, New York, among others, will address the Pottawattamie County Medical Society, April 12, in Council Bluffs; his subject will be "A Proposed Program for Venereal Disease Control." Dr. Edward N. Cook, Rochester, Minn., among others, addressed the society March 22 on "The Use of Mandelic Acid in the Treatment of Urinary Infections."

KANSAS

Executive Secretary for Sedgwick County.—Mr. Jack Austin, Blackwell, Okla., has been appointed executive secretary of the Sedgwick County Medical Society, Wichita, succeeding Mac F. Cahal, who resigned to become field secretary of the American Roentgen Ray Society, American Radium Society, Radiological Society of North America and the American College of Radiology. Since 1935 Mr. Austin has been city editor of the *Blackwell Tribune*.

Neuropsychiatry in General Practice.—The third annual graduate course on neuropsychiatry in general practice will be held at the Memminger Clinic, Topeka, April 19-25. In addition to members of the clinic, the guest speakers will be:

Dr. Franklin G. Ebaugh, professor of psychiatry, University of Colorado School of Medicine, Denver.

Dr. Winchell McK. Craig, associate professor of neurosurgery, University of Minnesota Graduate School of Medicine, Rochester.

Dr. James W. Kernohan, associate professor of pathology, University of Minnesota Graduate School of Medicine, Rochester.

KENTUCKY

Society News.—At a meeting of the Third District Medical Society in Bowling Green, March 17, the speakers included Drs. William R. Cate and Robert E. Sullivan, Nashville, Tenn., on "Thyrototoxic Heart Disease" and "Treatment of Acute Upper Respiratory Infections" respectively. —A bicounty medical society for Bracken and Pendleton counties was organized at a meeting in Falmouth, March 18. Dr. James M. Stevenson, Brooksville, was elected president and Dr. William A. McKenney, Falmouth, secretary. —Dr. Russell E. Teague, Paducah, addressed the McCracken County Medical Society, Paducah, March 24, on control of syphilis. —Dr. Caspar L. Woodbridge, Middlesboro, presented a paper on traumatic corneal ulcer at a meeting of the Bell County Medical Society, Middlesboro, March 19.

LOUISIANA

Personal.—Sir Aldo Castellani has returned to his duties as professor of tropical medicine at Louisiana State University Medical Center, New Orleans. Dr. Castellani was in charge of the health and sanitation of the Italian army during the campaign in Ethiopia.

Society News.—At a meeting of the East and West Feliciana Bi-Parish Medical Society in Jackson, February 3, Drs. H. Guy Riche, Baton Rouge, discussed "Heart Disease in Pregnancy"; Edgar Burns, New Orleans, "Stone Formation in the Urinary Tract," and Guy L. Odom, Jackson, "Artificial Therapy in Paresis or Neurosyphilis." —The LaFourche Valley Medical Society was addressed in Thibodaux, February 10, by Drs. John G. Menville, New Orleans, on "Treatment of Infection of the Lower Urinary Tract" and Percy H. Le Blanc, Donaldville, "Bacteriophage as a Therapeutic Agent." —Dr. Sydney Jacobs, New Orleans, among others, addressed the Tuberculosis and Public Health Association of Louisiana, January 27, on "The Present Outlook for the Tuberculous Patient." —Dr. John O. McReynolds, Dallas, Texas, addressed the New Orleans Eye, Ear, Nose and Throat Club recently on various ophthalmic operations.

MAINE

Radium Placed at Disposal of City.—A supply of 110 mg. of radium has been made available to the city of Portland for use in the treatment at the Farrington Hospital of cancer patients who are without funds. The radium is the property of Dr. Adam P. Leighton, who is lending it as a contribution to the national campaign against cancer. Dr. Leighton is secretary of the state board of registration in medicine.

MARYLAND

Society News.—Dr. Claud C. Smink discussed chronic arthritis before the Maryland Academy of Medicine and Surgery, Baltimore, March 16. Other speakers included Drs. Thomas B. Aycock on "Present Status of the Surgical Treatment of Hypertension" and Edgar B. Friedenwald and George B. Mansdorfer, "Spontaneous Pneumothorax."

MASSACHUSETTS

Prize for Paper on Gynecology.—The New England Obstetrical and Gynecological Society has recently established an annual prize of \$250 for the best essay on either obstetrics or gynecology. Interns serving at any hospital in New England having an obstetric service are eligible. Members of the executive committee of the society will act as judges.

Lectures on Alcoholism.—The social service committee of the Boston City Hospital and the advisory committee for the study of alcoholism began a series of lectures on alcoholism at the Mallory Institute of Pathology, March 15. Coming lectures include:

Dr. Leo Alexander, April 12, Neuropathological Aspects of Alcoholism.
Dr. Timothy Leary, April 26, Alcoholism as a Medicolegal Problem.
Miss Mildred G. Gray, May 3, assistant in pharmacology, Boston University School of Medicine, The Physiological Effects of Alcohol.
Dr. Jackson M. Thomas, May 10, Alcoholism and Mental Disease.
Dr. Robert E. Fleming, May 17, Treatment of Chronic Alcoholism.
Miss Mabel R. Wilson, director of medical social service, Boston City Hospital, May 24, Alcoholism as a Problem in Medical Social Service.

The advisory committee is sponsoring a WPA survey of alcoholic patients at the hospital.

MICHIGAN

Proposed National Department of Health.—The Michigan State Medical Society adopted a resolution recommending, in the event of any reorganizing process affecting the U. S. Public Health Service, the creation of a department of public health in the national government to include all activities in the field of preventive medicine now performed by the various departments. This action was taken in support of a similar action of the Board of Trustees of the American Medical Association at a meeting early in January. The society further recommends that the supervision and direction of such a department should be in the hands of a competently trained physician, experienced in executive administration.

Society News.—The Washtenaw County Medical Society and the Washtenaw County Bar Association were guests of the Ann Arbor Lawyers Association, February 18; Lieut. Harold Mulbar of the Michigan State Police discussed the lie detector.—Dr. Paul B. Magnuson, Chicago, discussed "Fractures of the Neck of the Femur" before the Kalamazoo Academy of Medicine, February 16.—Dr. Herbert Worley Kendell, Dayton, Ohio, discussed "Present Status of Fever Therapy" before the Calhoun County Medical Society, Battle Creek, March 2.—Dr. Norman F. Miller, professor of obstetrics and gynecology, University of Michigan Medical School, Ann Arbor, March 3, addressed the Genesee County Medical Society on acute conditions in the lower part of the abdomen in women.

MISSOURI

Dr. Sachs Honored.—Dr. Ernest Sachs, professor of clinical neurologic surgery at Washington University School of Medicine, St. Louis, since 1919, when the post was created, was honored at a dinner at the Jefferson Hotel, March 20. A silver plaque bearing a reproduction of his favorite surgical instrument was presented to him and the following inscription: "From the Fellows he has trained in neurologic surgery during his first twenty-five years of continuous teaching, 1912-1937." Major Philip P. Green, U. S. Army, Hot Springs National Park, one of the twenty graduate fellows whom Dr. Sachs has trained, made the presentation. Dr. Leonard T. Furlow, St. Louis, another of the group, presided at the dinner, and the speakers included Drs. Barney Brooks, Nashville, Tenn., and Evarts A. Graham and Sidney I. Schwab, St. Louis. Dr. Sachs, who is 58, was graduated from Johns Hopkins University School of Medicine in 1904 and holds the first professorship of neurologic surgery created in any American university.

Gifts for Cancer Research.—St. Louis University School of Medicine, St. Louis, has received two gifts from anonymous donors to aid in cancer research and treatment, according to the *St. Louis Globe Democrat*. One, consisting of 705 acres of farm land, valued at about \$75,000, in Mississippi County, Ark., will not be available for use by the school until the death of the donors; the second is \$7,000 to purchase radium for the benefit of indigent cancer patients. According to the

report, the fund will be sufficient to purchase 180 mg. of radium in the form of needles and accessory equipment with servicing for five years. It will be named the Margaret and Elizabeth Radium Service and is open to donations from other persons. This will be the first radium the school has owned; its supply has been rented in the past. The income from the land will be used to establish a foundation for research on cancer. Both gifts will make it possible to augment the cancer program at the school, which is under the supervision of Dr. Albert E. Casey, associate professor and chairman of the department of pathology and other members of the cancer study committee: Drs. Charles F. Sherwin, chairman, Goronwy O. Brown, John Grey Jones, Lex G. McCutcheon and Norman Tobias.

MONTANA

Personal.—Dr. Charles E. K. Vidal has retired as medical superintendent of the Montana State Tuberculosis Sanatorium, Deer Lodge, effective May 1. He has been associated with the sanatorium for eighteen years. Dr. Vidal was honored at a meeting of the Mount Powell Medical Society, March 15, in Galen.

NEVADA

Society News.—Dr. Louis E. Lombardi, Reno, was elected president of the Washoe County Medical Society recently, and Dr. Turyman C. Harper, Reno, secretary.

Annual Registration Due May 1.—All persons holding licenses to practice medicine in Nevada are required by law to pay annually to the treasurer of the Board of Medical Examiners, on or before May 1, a tax of \$2. Failure to do so operates to forfeit a licentiate's right to practice medicine, and his license to practice can be reinstated thereafter only on the payment of a \$10 penalty.

NEW JERSEY

Mosquito Control Report.—The New Jersey Mosquito Extermination Association announces that it will receive applications for copies of the proceedings of its annual meeting up to May 10. Remit 75 cents to the secretary, Thomas J. Headlee, State Experiment Station, New Brunswick. The usual review of mosquito control work throughout the world will be included. Publication is scheduled for June 10.

Graduate Lectures.—A series of graduate lectures in medicine is being presented for the Atlantic and Cape May county medical societies at the Hotel Chalfonte, Atlantic City, with Philadelphia physicians as the speakers. The list is as follows:

Dr. David Riesman, Recent Advances in Medicine, March 10.
Dr. John A. Kolmer, Serum Therapy, March 17, and The Present Status of Vaccine Therapy, March 24.
Dr. Richard A. Kern, Present Day Use of Nonspecific Protein Therapy, March 31.
Dr. John Claxton Gittings, Prevention of Nutritional Disorders and Deficiency Diseases, April 7.
Dr. Ralph M. Tyson, Prevention of Communicable Diseases in Childhood, April 14.

NEW YORK

Personal.—Dr. John T. Howell, Newburgh, recently completed fifty years in the practice of medicine. He has been president of both the Orange County and Newburgh Bay medical societies and has written a history of the county society. He organized the Newburgh Medical Library and has been its only librarian, according to the *New York State Journal of Medicine*.

Unlicensed Practitioner Convicted.—The state board of medical examiners recently reported that Charles Richardson, Rochester, was convicted of practicing without a license January 29 and sentence was suspended. Newspapers reported that Richardson was the proprietor of the "Richardson Sanatorium," where he happened to give medical advice to an investigator for the state.

New York City

Seventh Harvey Lecture.—Dr. Cyril N. H. Long, professor of physiologic chemistry, Yale University School of Medicine, New Haven, Conn., will deliver the seventh Harvey Society Lecture of the current series at the New York Academy of Medicine, April 12. His subject will be "The Influence of the Pituitary and Adrenal Glands on Pancreatic Diabetes."

Hospital News.—The Arthur B. Duell Facial Palsy Clinic has been established at the Manhattan Eye, Ear and Throat Hospital in memory of the late Dr. Duell, who founded a clinic for facial palsy in the hospital in 1933 and was in charge of it until his death. Dr. Thomas G. Tickle, a former associate of Dr. Duell, is in charge of the clinic and will offer a course in the surgical technic and treatment of facial paralysis.

Physicist Killed by X-Ray Machine.—Wesley M. Coates, Ph.D., physicist of Crocker Institute for Cancer Research, Columbia University, was killed instantly, March 20, when he accidentally came in contact with the power lines of the new million-volt x-ray machine installed in Presbyterian Hospital. Dr. Coates received his academic training at the University of California, was a member of the department of physics at Columbia, and during the past year had assisted in the installation of the new x-ray apparatus, which was completed only a few weeks ago. He was about 35 years of age.

Lectures on Bright's Disease and Hypertension.—A series of lectures is being offered this month at New York Post-Graduate Medical School and Hospital on "Bright's Disease and Hypertension." Dr. Will C. Spain gave the first lecture, on "Allergy as a Cause of Migraine and Hypertensive Headache," and Dr. William Goldring the second, on "Modern Aspects of Renal Function in Relation to Bright's Disease." Coming lectures are:

Dr. Irvine H. Page, Surgical Treatment of Hypertension, April 15.
Dr. Albert A. Epstein, So-Called Lipoid Nephrosis or Diabetes Albuminuricus, April 22.

Dr. Arthur M. Fishberg, The Heart in Bright's Disease, April 29.

Personal.—Dr. Meredith Fairfax Campbell, clinical professor of urology, New York University College of Medicine, has been promoted to be professor of urology, succeeding Dr. Alfred Townsend Osgood, who has become professor emeritus.—Dr. James P. Croce, clinical professor of internal medicine at the New York Polyclinic Medical School and Hospital, has been made professor of internal medicine and Dr. Howard Sheffield Jeck, New York, has been appointed professor of urology.—Dr. Richard H. Bennett has been appointed medical director of the Brooklyn Home for Consumptives, succeeding the late Dr. Luther F. Warren. Dr. Bennett has been senior attending physician.—Homer Folks, LL.D., secretary of the State Charities Aid Association since 1893, was honored at a dinner at the Waldorf Astoria, February 18, celebrating his seventieth birthday.—Dr. Henry Joachim, Brooklyn, has been appointed by Governor Lehman a member of the state industrial council to succeed Dr. William Linder.

OHIO

Hospital News.—Dr. Louis N. Katz, director of cardiovascular research, Michael Reese Hospital, Chicago, lectured at the research institute of the Jewish Hospital, Cincinnati, recently on "Recent Observations of the Coronary Circulation."

Dr. Rous Lectures in Cincinnati.—Dr. Francis Peyton Rous of the Rockefeller Institute for Medical Research delivered a lecture at the University of Cincinnati College of Medicine, March 29, on "Present Knowledge of the Causation of Tumors."

Postgraduate Day at Youngstown.—The Mahoning County Medical Society will hold its tenth annual "Postgraduate Day" April 20 with speakers from the University of Michigan Medical School, Ann Arbor. Following is the tentative program:

Dr. Albert C. Furstenberg, A Clinical and Anatomical Study of Inflammatory Processes in the Mouth and Pharynx.

Dr. Frank N. Wilson, Coronary Occlusion; Cardiac Failure.

Dr. Frederick A. Collier, Administration of Fluids to the Sick Patient; Surgical Aspects of Gallbladder Disease.

Dr. Cameron Haight, Treatment of Empyema; Surgical Management of Pulmonary Tuberculosis.

Dr. John M. Sheldon, Skin Hypersensitiveness; A Consideration of the Diagnostic Criteria and Specific Management for Allergic Disease.

PENNSYLVANIA

Fourteen Physicians in the Legislature.—The *Pennsylvania Medical Journal* reports that fourteen physicians are members of the legislature. In the senate are Drs. Leroy E. Chapman, Warren; George A. Deitrick, Sunbury; Patrick J. Henney, McKees Rocks; I. Dana Kahle, Knox; Leo C. Mundy, Wilkes-Barre, and George Woodward, Philadelphia. In the house of representatives are Drs. Samuel P. Boyer, Johnstown; Emlyn T. Davies, Old Forge; Audley O. Hindman, Burgettstown; Albert F. Merrell, Hallstead; George J. Sarraf, Pittsburgh; William W. Serrill, Kellettsville; Thomas E. Shea, Philadelphia, and Albert J. Valibus, Edwardsville.

Philadelphia

Society News.—Dr. John O. Bower, among others, addressed the Philadelphia Academy of Surgery, April 5, on "Prevention of Induced Spreading Peritonitis Complicating Acute Perforative Appendicitis."—The program of the Eastern Pennsylvania chapter of the Society of American Bacteriologists, February 23, included the following speakers: Dr. Baldwin H. E. W. Lucke, on "The Relation of Viruses

to Neoplastic Diseases"; Dr. Joseph Stokes Jr., "Studies in Active Immunization Against Human Influenza"; Henry W. Scherp, Ph.D., Dr. Irving J. Wolman, Earl W. Florsdorf, Ph.D., and Mr. D. R. Shaw, "Studies on Concentration and Preservation of the Virus of Poliomyelitis and Influenza," and Dr. John A. Kolmer, Miss Clara Kast and Miss Anna M. Rule, "Attempts at the Cultivation of the Virus of Poliomyelitis" and "Attempts to Produce Poliomyelitis in Ferrets and Other Lower Animals."

TENNESSEE

Medical Activities Among Flood Refugees.—The *Memphis Medical Journal* for March contains a preliminary report of medical activities among refugees from the Ohio and Mississippi floods in late January and early February, that of the personnel committee of the Memphis and Shelby County Medical Society. A school was converted into an emergency hospital and offices were established there for the committees in charge. From this center medical and clerical staffs were organized for the emergency aid stations at the fair grounds and the municipal auditorium, a pediatric emergency hospital in the juvenile court building and various other units at points at which refugees were concentrated. Physicians were furnished to make sick calls twice a day in all barracks (fifteen or twenty in all) and outpatient clinics were set up in several of them. A mobile emergency unit was organized with eleven young physicians, known as the "flying squadron," to assist in emergencies wherever needed. The Drug Club of Memphis had charge of organizing and distributing drugs from a central store room at the school-hospital. Dentists set up equipment at the fair grounds aid station and had dentists holding clinics at regular hours. The available ambulances, including private ones as well as others furnished by the army and the Tennessee Valley Administration, were organized into a single unit, with a central starting stand equipped with telephones and operators. The report pays special tribute to the medical students of the University of Tennessee, who worked with the department of health and the Memphis and Shelby County Medical Society. A complete hospital unit was brought to Memphis by Dr. Eugene L. Bishop, medical officer of the TVA, from Knoxville and placed at the disposal of the society. The state commissioner of health also brought a contingent to aid the health department in its preventive work. The society's hospital committee reported that from the arrival of the refugees up to February 16 there had been 1,657 patients hospitalized. The largest number hospitalized any one day was 813 on February 4. Beds were available at twenty-one different places.

TEXAS

Society News.—Dr. Eugene V. Powell, Temple, was elected president of the Texas Radiological Society at its annual meeting in Abilene recently. Dr. Leon J. Menville, New Orleans, conducted a diagnostic clinic on bone tumors and made an address at an evening banquet.—Papers on control of syphilis were presented at a meeting of the Dallas County Medical Society, Dallas, April 8, by Drs. James W. Bass, Everett C. Fox and Arthur G. Schoch. In addition, Dr. Walter G. Reddick spoke on amebiasis and Dr. Sim Driver on bone tumors.

GENERAL

Place of Pediatric Meeting Changed.—The American Pediatric Society will hold its annual meeting at the Homestead, Hot Springs, Va., April 29-May 1. The meeting was previously scheduled to be held in University.

Impostor "Brown"—Warning.—A Buffalo physician reports that a man posing as a clinical pathologist under the name Brown has recently victimized a member of the staff of the Buffalo City Hospital by persuading him to endorse a check for \$50. The story resembles closely a report published in *THE JOURNAL*, February 13 (page 567). The man said that he had automobile trouble and needed ready cash. In Buffalo he was looking for a technician in bacteriology, saying that he was pathologist and laboratory director for a large hospital in Columbus, Ohio. As in Detroit, he presented as his only identification a bank book showing deposits. According to the report from Buffalo he had a large broad nose, thick lips and beautiful white teeth. His skin was thick and deeply furrowed. His forehead receded and the occiput tapered backward. The hair was black, short, curly, wavy and polished, with some gray in it. His skin was not clear white but rather a pale yellow. Similar reports have been received from Chicago and Davenport, Iowa.

Society News.—Dr. Charles S. Holt, Fort Smith, Ark., was elected president of the Missouri Pacific Medical Association,

January 29, at its annual meeting in Little Rock; Drs. Robert N. Canaday, Dupon, Ill., and William T. Rance, Omaha, vice presidents, and Joseph A. Lembeck, St. Louis, reelected secretary.—The American Physiotherapy Association, an organization of technicians, will meet in St. Paul at the Hotel Lowry, June 27-July 1.—The seventh National Conference on Visual Education and Film Exhibition will be held in Chicago, June 21-24, at the Francis W. Parker School, 330 Webster Avenue.—Dr. Thomas C. Davison, Atlanta, was chosen president-elect of the Southeastern Surgical Congress at its annual meeting in Charlotte, N. C., March 8-10, and Dr. Fred W. Rankin, Lexington, Ky., was installed as president. Dr. Julian L. Rawls, Norfolk, Va., was elected vice president and Dr. Benjamin T. Beasley, Atlanta, was reelected secretary. Next year's meeting will be in Louisville, Ky.—Dr. Frederick L. Reichert, San Francisco, was chosen president of the Pacific Coast Surgical Association at its annual convention in Victoria, B. C., February 27, and Dr. Harry Glenn Bell, San Francisco, reelected secretary.

Meetings at Atlantic City.—The thirteenth scientific session of the American Heart Association will be held in Atlantic City, N. J., June 7-8, at Haddon Hall.—The American Neisserian Medical Society will hold its annual meeting June 8 at the Senator, Atlantic City.—The Society for the Study of Asthma and Allied Conditions will hold its spring meeting at the Chalfonte-Haddon Hall, Atlantic City, May 1.—The annual luncheon of the Phi Lambda Kappa medical fraternity will be held Wednesday, June 9, at the Ritz-Carlton Hotel, Atlantic City; headquarters for the fraternity will be maintained at the same hotel during the annual session of the American Medical Association.—The American Committee on Maternal Welfare, Inc., will have a luncheon meeting at the Hotel Dennis, Atlantic City, Wednesday, June 9, at 12:15 p. m. Addresses will be made by Drs. Malcolm T. MacEachern, Chicago; Herman G. Weiskotten, Syracuse, N. Y., and Ray Lyman Wilbur, Stanford University, Calif. It is requested that tickets be purchased directly from the hotel and well in advance, so that the service will be expedited.—The annual meeting of the American Gastro-Enterological Society will be held in Atlantic City, June 7-8. Dr. Russell S. Boles, Philadelphia, is the secretary.

Mortality Rates in Eighty-Six Cities in 1936.—The U. S. Bureau of the Census reports that the death rate in eighty-six major cities of the United States for 1936 was 12.3 per thousand of estimated population, as compared with 11.4 for 1935. The actual number of deaths was 458,754, compared with 427,736 in 1935. Three unusual features of the 1936 figures are pointed out. Deaths during February, March and April were considerably greater than during the corresponding months of the previous year; a widespread heat wave during July 1936 caused the death rate to reach 17 in that month, and during the last week of 1936 there was a sharp increase in deaths, reflecting the general increase in deaths from influenza and pneumonia during the past winter. The cities with the highest rates were Nashville, Tenn., 19.2; Washington, D. C., 18.7; New Orleans, 18.6, and Memphis, 18. Among cities with a rate appreciably lower than the general rate were South Bend, Ind., 8.1; Yonkers, N. Y., 8.3; Flint, Mich., 8.2; Detroit, 8.4, and Akron, Ohio, 8.4. New York and Chicago had the same rate, 10.8. The provisional infant mortality rate was 51 per thousand live births. The final rate for 1935 was 54, but since the provisional rate generally tends to be somewhat lower than the final rate there is no reason to believe that there has been an important reduction in infant mortality, the bureau's report states.

Annual Report of Commonwealth Fund.—During 1936 the Commonwealth Fund of New York expended \$1,967,153, more than two thirds of which was for medical research and the improvement of medical service in rural areas. For the first time in several years a large share went to New York institutions, according to the *New York Times*. The largest appropriation was a gift of \$250,000 to Columbia University College of Physicians and Surgeons to aid in enlarging laboratory facilities for graduate medical education. Funds to provide full time psychiatric consultation for staff and students of pediatrics were awarded to Babies Hospital and New York Hospital and aid was continued to a study of medical education in New York hospitals sponsored by the New York Academy of Medicine. Other appropriations were made to New York Hospital for a study of rheumatic fever; Neurological Institute for study of the structure and development of the brain; to Bellevue Hospital for study of tuberculosis and to the New York City Department of Health for its pneumonia serum project. Johns Hopkins University School of Medicine, Baltimore, received funds to finance studies of high blood pressure uncomplicated by organic disease, of the chemical nature

of insulin and of placental extract in the treatment of measles and other virus infections. Scholarships were awarded to physicians in Tennessee, Mississippi and the northern New England states for periods of graduate study in Harvard, Tulane, Vanderbilt and other medical schools. Continuing its program of building small hospitals in cooperation with local authorities, the fund completed the seventh of these hospitals at Kingsport, Tenn., began the eighth at Tupelo, Miss., and awarded the ninth to Ada, Okla. Aid was also given to improvement of public health service in Tennessee, Mississippi and Massachusetts.

American College of Physicians.—The twenty-first annual session of the American College of Physicians will be held at the New Jefferson Hotel, St. Louis, April 19-23. A special feature of the program is a course of morning lectures, consisting of three symposiums on tuberculosis, infectious diseases and diabetes mellitus, and a mixed program. A departure this year is the series of round table discussions, which have been arranged so as not to conflict with the morning lectures and hospital clinics. Following are the leaders in the discussions and the topics:

- Dr. Elliott P. Joslin, clinical professor of medicine, Harvard University Medical School, Boston, Diabetes Mellitus.
- Dr. Thomas Parran, surgeon general, U. S. Public Health Service, Washington, D. C., Public Health Aspects of Syphilis.
- Dr. Samuel A. Levine, assistant professor of medicine, Harvard University Medical School, Boston, Cardiovascular Problems.
- Dr. James Alexander Miller, professor of clinical medicine, Columbia University College of Physicians and Surgeons, New York, Pulmonary Tuberculosis.
- Dr. Walter C. Alvarez, professor of medicine, University of Minnesota Graduate School of Medicine, Rochester.
- Dr. Henry E. McLency, associate professor of public health, Vanderbilt University School of Medicine, Nashville, Tennessee, Amebiasis and Malaria, Diagnosis and Treatment.
- Dr. Robert A. Cooke, assistant professor of clinical medicine, Cornell University Medical College, New York, Allergy.
- Dr. O. H. Perry Pepper, professor of medicine, University of Pennsylvania School of Medicine, Philadelphia, Diseases of the Blood.
- Dr. Udo J. Wile, professor of dermatology and syphilology, University of Michigan Medical School, Ann Arbor, Treatment of Various Phases of Syphilis.

The annual smoker will be held Monday evening. The John Phillips Memorial Medal for 1936-1937 will be presented during the convocation ceremony Wednesday evening to Dr. Richard E. Shope of the Rockefeller Institute for Medical Research, Princeton, N. J. Following this ceremony John Dewey, LL.D., professor emeritus of philosophy, Columbia University, New York, will deliver the convocational oration on "The Unity of Man." Thursday morning a pilgrimage to the grave of William Beaumont is planned. In the evening Dr. Alfred Stengel, Philadelphia, will be the toastmaster at the annual banquet. The speaker will be Dr. Logan Clendening, Kansas City, Mo., on "American Medical Shrines."

FOREIGN

Personal.—Dr. John Stirling Young, professor of pathology in the Queen's University, Belfast, has been appointed professor of pathology at the University of Aberdeen, Scotland, to succeed Prof. Theodore Shennan, who resigned.—Sir Joseph Barcroft, professor of physiology at the University of Cambridge, will retire at the end of September, the *Lancet* reports, and will be succeeded by Dr. Edgar Douglas Adrian, Foulerton professor of the Royal Society and fellow of Trinity College, Cambridge. Dr. Adrian shared the Nobel Prize in medicine and physiology with Sir Charles Sherrington in 1932.

Society News.—The International Congress of Military Medicine and Pharmacy will be held in Bucharest, June 2-10. The secretary-general is M. Popescu Buzeu, Institut Sanitary Militar, Bucarest, Ile, Rumania.—The sixth International Congress on Rheumatism, sponsored by the International League Against Rheumatism, will be held in Oxford, England, about the end of March 1938. Dr. J. F. L. Van Breemen, Keizersgracht 489/491, Amsterdam, is the secretary.—The fourth International Congress on the History of Science will be held in Prague, September 22-27.—The Medical Society of Vienna will celebrate its one hundredth anniversary with clinics and lectures from May 19 to May 29. Among those who will take part in the program will be:

- Dr. Paul Clairmont, Zurich, Actinomycosis.
- Dr. R. Leriche, Strasbourg, New Principles in Surgery.
- Dr. Friedrich von Müller, Munich, The Arthritic Diathesis.
- Dr. Otto Naegeli, Zurich, Significance of Diagnosis of Disease Groups, with Special Reference to Diseases Difficult to Recognize.
- Dr. Erich Lexer, Munich, Wound Infections.
- Dr. Walter Stoeckel, Berlin, Prophylactic Work of the Gynecologist.
- Dr. Ferdinand Sauerbruch, Berlin, Development of Medicine in the Nineteenth and Twentieth Centuries.

Among other speakers whose subjects were not announced were Drs. Karl F. Wenckebach, Anton von Eiselsberg and Julius Wagner-Jauregg, all of Vienna. Various special societies will hold meetings during the period of celebration.

March 13, 1937.

Special Tax Proposed for Foods with Health Claims

The attempts of the British Medical Association to grapple with the nostrum evil have been described before (*THE JOURNAL*, Dec. 5, 1936, p. 1900). Immense sums are spent on these "patent medicines," for which more or less fraudulent claims are widely advertised. A bill, made so moderate as to secure the support of newspaper and advertising associations and representatives of the drug trade, which would therefore have checked only the worst evils, was lost in consequence of misleading propaganda (*THE JOURNAL*, May 23, 1936, p. 1829). A tax is levied on "patent medicines" from which a considerable revenue is derived. But in these days when the government is so active in promoting the health of the people it cannot continue to ignore the evil of fraudulent claims.

The reform of medicine stamp duties has been the subject of report of a select committee of the House of Commons. It proposed that preparations or substances of any sort which are recommended, held out or advertised in any way for the prevention, cure or relief of any human ailment shall be liable to duty. The revised scale of duty suggested is graded from 0.25 cent to 2 cents for articles costing up to 12 cents and 2 cents for every 12 cents over that price. If it is decided to adopt an ad valorem duty the committee recommends 16⅓ per cent. It is suggested that exemption should be granted to all medicines recommended and sold solely to physicians or dentists or supplied to pharmacists for use in dispensing physicians' prescriptions. The committee also advises considering the advisability of taxing foods and certain appliances, beverages and other preparations widely advertised as having properties beneficial to health. The report gives two estimates as to the turnover of those engaged in the manufacture of "patent medicines"—a conservative one of \$100,000,000 and a higher one of \$140,000,000, depending on an unknown element. On the basis of the former, the duty of 16⅓ per cent would yield \$16,500,000. Should control of the trade in medicines be deemed desirable for the protection of the public, the committee believes that the best method of achieving this would be a system of examination and registration of all advertised medicines and appliances. This last recommendation is too weak. It does not meet the worst evils, such as nostrums advertised for the cure of tuberculosis or diabetes, which should not be allowed. Moreover, registration would be thought by the ignorant to be some sort of a guaranty of respectability.

The Diagnosis and Treatment of Acute Poliomyelitis

The Ministry of Health has issued a revised pamphlet on acute poliomyelitis in which recent advances in the pathology, diagnosis and treatment are reviewed. It is pointed out that the initial symptoms are indistinguishable from those of other infections, but signs of lesions of the central nervous system may appear rapidly. The following signs are confirmatory of a provisional diagnosis in the preparalytic stage: *Spinal sign*: The patient is disinclined to bend the head forward on account of the pain produced, and there is resistance to passive anterior flexion of the neck. When he is raised by the shoulders the head falls backward and he cannot easily bring it forward again. A simple way of eliciting this sign is to ask him to kiss his knees. *Amoss's sign*: This is a useful modification of the spinal sign in older children. When placed in the sitting posture and asked to fold his arms the child may attempt to

do so but quickly reverts to the position in which part of the body weight is borne by the arms, which thus makes three legs of a tripod, the spine being the third.

When stiffness of the spine or resistance of the neck to passive flexion supervenes, associated with headache and fever, a provisional diagnosis is justified and the cerebrospinal fluid should be examined. As regards the poliencephalitic form, implication of the brain, medulla, meninges or spinal nerves may give rise to symptoms such as bulbar paralysis or speech disturbances. The differential diagnosis from lethargic encephalitis, cerebrospinal meningitis, tuberculous meningitis or septic meningitis is made by the previous history and the presence of other cases in the vicinity, with examination of the cerebrospinal fluid.

The results of serum treatment reported by different observers are contradictory. American workers have been skeptical, in view of the grave after-effects. The Ministry of Health is sufficiently impressed to give the following rules: 1. Convalescent serum should be given as early as possible; i. e., immediately after any sign of spinal involvement and lumbar puncture have confirmed the diagnosis. 2. The serum may be administered at the time of, or as soon as possible after, diagnostic lumbar puncture, provided the quantity injected does not exceed the amount of fluid withdrawn. A suitable intrathecal dose is about 20 cc., with 30-50 cc. given by other routes (intravenous or intramuscular). If no improvement is observed, the administration may be repeated within twenty-four hours. 3. The serum should be given only by an experienced physician or a clinical pathologist versed in the technique of intrathecal and intravenous administration.

Precautions against infection should be taken. It is difficult to say how long a patient remains infectious, but the ministry recommends isolation from other children for six weeks and limiting association with him to that necessary for care and nursing. Those in attendance should bear in mind that infection may be conveyed from the nasopharyngeal secretions, urine and excreta. A strictly surgical standard of nursing is therefore indicated, with use of nasal sprays or douches and gargling. Children in the affected household should remain away from school for three weeks after isolation of the patient. The balance of evidence is in favor of not closing residential schools on the appearance of poliomyelitis, which would only more widely distribute any potential infection.

Asthma Research

The report of the Asthma Research Council for 1936 has been published. The council cannot offer individual advice but is gratified to hear from all parts of the world that patients are deriving benefit from the exercises described in their pamphlet (reviewed in a previous letter). The treatment at the centers of the council in various hospitals is described. At St. Mary's Hospital, London, the treatment may be divided into (1) desensitization, (2) antibacterial and (3) psychologic. The psychologic factor has always been regarded as of great interest at this clinic. For many years it has been clear that a psychologic upset may precipitate an attack of asthma, urticaria or eczema and that, on the other hand, these diseases may produce a psychologic upset. Dr. Wittkower believes not only that asthmatic persons tend to be psychologically abnormal but that asthma and allied diseases tend to occur particularly in those whose lives have been psychologically blighted at an early age. Further he holds, in common with most psychiatrists, that asthma and eczema are often symbolic of some mental trouble and that therefore the physical disease may be a relief from neural tension, such as anxiety, and so may be an advantage in affording escape from something worse. While admitting that such cases occur, the Asthma Research Clinic as a whole does not accept this as a general principle.

Sensitization to mold spores is found to play a big part in locality asthma. Warned by previous difficulties in myologic research, the clinic has treated these cases by dust collected in the patient's house by a vacuum cleaner. It has not succeeded in making dust into a stock extract for testing purposes or a stock vaccine for treatment, since the ingredients of the dust depend almost entirely on local factors. A number of successes have been scored with "autogenous" dust extracts, but there have also been many failures and research is proceeding on this point.

The separate hay fever clinic commences at the beginning of March each year and ends in July. There has been a great extension of the principle of self inoculation, on the whole with satisfactory results. Those who are temperamentally or intellectually unsuited for self inoculation receive all their treatment at the clinic. In addition to this prophylactic desensitization, many apply for treatment during the actual season. These have received the customary small doses, often with marked benefit. This is taken to show that there are two immunologic principles, for the slight stimulus from a dose of 100 units cannot act in the same way as the draining away or neutralizing of sensitivity by repeated doses of 100,000 units. This duality is confirmed by the recent work of Coke and his collaborators in America. Their results indicate that specific pollen therapy may engender a curious type of antibody which inhibits the reaction of sensitized cells to the specific pollen extract, and they report favorably on the results of transfusion of whole blood or serum containing this antibody in untreated cases of hay fever.

Criticism of Social Insurance Law by One of the Insured

The medical profession in France is so accustomed to read criticisms from the physician's standpoint of the recently (1935) modified social insurance law that it appeared to be of interest to hear the other side; i. e., how the insured worker looks at the law. In the effort to do so an intelligent electrician was asked to look over the various paragraphs of a "guide for physicians" recently issued by the Central Federation of Medical Syndicates. The paragraphs and corresponding suggestions of the insured worker are as follows:

Paragraph 1. The insured worker reimburses the medical attendant directly for all services and the latter signs the "sickness blank" stating the sum paid.

Criticism: It frequently happens that the insured worker does not have sufficient funds to pay immediately for medical services; hence it would be better for the caisses or disbursing bureaus of the social insurance organization to pay the physician and to deduct the sum paid from the indemnity of the insured. If the insured cannot pay the physician, the latter is obliged by the law to refuse to sign the certificate. The result is that frequently the insured does not call a physician, because unable to pay for the services in advance, and hence many do not receive the needed medical attention.

Paragraph 2. If the physician treating the insured worker desires to call a consultant, a special blank must be given the insured worker by the attending physician and this must be presented to the local caisse, who gives the necessary permission. In emergency cases this formality is temporarily waived by the caisse.

Criticism: The caisses reimburse the insured only an insignificant sum for consultants. For example, in the city where the electrician lives the expense of a consultation is about 200 francs (about \$10) and the insured is reimbursed only to the extent of 27 francs. In addition, only two consultations are allowed in a given case.

Paragraph 3. If an illness lasts more than six months, all indemnity ceases except in the cases in which the insured is given an invalidity certificate. A relapse that takes place within the two months following "apparent cure" is considered a new illness. The insured can then be given a second six months indemnity period if he files a certificate to the effect that he had been "apparently cured" at the termination of the first six months period.

Criticism: There ought not to be any limit to the period during which an insured person should be indemnified. In a great many cases, to limit indemnity to a six or even twelve months period works a hardship on many of the younger insured workers, some of whom suffer as the result of hereditary disease. In general, one cannot set a date at which a chronic ailment can be considered as "apparently cured."

General criticism: The indemnities allowed by various caisses vary greatly; for example, the insured electrician paid 300 francs for his daughter's tonsillectomy and was reimbursed only 76 francs; one of his friends received an indemnity of 123 francs and another 127 francs in a similar case. The funds of the social insurance organization should not be used to help out a deficit in the government budget, because there will be no money left when the period arrives to pay for old age insurance. There has been much criticism of the unwise investment of social insurance funds in securities and real estate of doubtful cash value.

The Cerebral Form of Mumps

Among the nervous complications of mumps, such as meningitis, meningo-encephalitis or neuritis, one can distinguish certain forms that occur toward the end of the infection or prior to the glandular manifestation or even independently of any other localization due to the virus of mumps. At the Oct. 9, 1936, meeting of the Société médicale des hôpitaux some interesting cases in which the onset resembled a psychosis were reported by Urechia and Elekes of Rumania. The first patient was a girl, aged 19 years, who had scarlatina at the age of 5. The present illness began suddenly June 12, 1935, with severe headache, insomnia, irritability and depression. Three days later, mental confusion with incoherence, agitation and hallucinations appeared. This condition, resembling an acute psychosis, persisted for two days more, at which time a left parotid swelling was noted, followed by a similar condition of the opposite parotid and of both submaxillary salivary glands. The mental confusion increased and the general condition became worse, the patient dying eight days after the incipient mental symptoms. The diagnosis was the primary cerebral form of mumps.

A second patient was a woman, aged 48, whose previous history revealed only a serofibrinous pleurisy at the age of 29 and occurrence of the menopause one year before the present illness. The latter began suddenly in the form of marked agitation of a maniacal type. Four days after the onset a left parotitis appeared, accompanied by signs of marked cardiac weakness and followed by involvement of the opposite side a few days later. Death from myocarditis occurred on the eleventh day after the onset of the mental symptoms.

These two cases show that mumps may be a far more serious infection than is generally believed.

Protection Against Carbon Monoxide Gas in Shelters During War

At the Dec. 22, 1936, meeting of the Académie de médecine, Dr. André Kling read a paper on protection against carbon monoxide gas in shelters during war. The explosion of projectiles sets free a large quantity of carbon monoxide gas. An airplane bomb weighing 200 pounds, containing about 106 pounds of tolite, liberates, in bursting, 31 cubic meters of carbon monoxide, a quantity capable of rendering fatal the air of a

space 12 feet high, 24 feet wide and over half a mile long. If a bomb explodes in the earth there is great danger of this noxious gas entering water, sewer and other conduits as well as subterranean shelters. Hence it is indispensable to determine the composition of the air of all shelters, whether at the front or in cities subjected to bombardment, to ascertain whether the air has not been contaminated. Dr. Kling, who is director of the Paris Municipal Laboratory, presented a method, the carbon monoxide content being determined with hopcalite, which was sufficiently accurate and which could be used by persons not having any knowledge of chemistry.

Staphylococemia Treated Successfully with Staphylococcus Anatoxin

The efficacy of the staphylococcus anatoxin as prepared according to the technic elaborated by Professor Ramon of the Pasteur Institute has been frequently referred to in these letters. A remarkable case of recovery from a severe generalized staphylococcal infection following the use of the anatoxin was reported at the Oct. 16, 1936, meeting of the Société médicale des hôpitaux by Pagniez, Plichet and Rendu. A man, aged 31, was admitted complaining of pain referred to the chest, diarrhea and fever accompanied by profuse perspiration, of three weeks' duration. Physical examination revealed only numerous crepitant râles over both lungs. There was a marked purulent expectoration. The clinical picture was that of a severe septicemia, the temperature varying from 103 to 104 F. accompanied by profuse perspiration, pains over several joints and diarrhea. A blood culture positive for staphylococci was obtained for the first time eighteen days after admission, and a second one four days later. The staphylococcus anatoxin was begun at this period, eleven injections of 2 cc. being given at intervals of eight days. The blood culture was negative following the fourth injection. Following drainage of multiple superficial foci of suppuration, containing a nonhemolytic *Staphylococcus aureus*, the patient made an uneventful recovery.

Anomalies in Basal Metabolism in Children

A paper representing determination of the metabolism rate in more than 200 children with thyroid or hypophyseal syndromes was read at the Dec. 22, 1936, meeting of the Académie de médecine by Mouriquand and the Enselmes. The cases were divided into groups as follows:

A. Hyperthyroid states. A certain number presented a marked tachycardia in addition to other typical symptoms, but the metabolism was normal. Other children presented a more typical picture of sympathetic disturbance. Quite often the metabolism rate was also normal in such cases. Finally, cases with very marked hyperthyroidism symptoms were examined and found to have a high metabolism rate up to 70 plus, ending fatally in one case.

B. Hypothyroid states. 1. Classic myxedematous type. In general, there is an average lowering in the metabolism rate to -30. 2. Hypothyroid type of myxedema, i. e., without skin infiltration, representing an attenuated form of the preceding. The average lowering of the metabolism was -18. 3. Dwarfism type. Here the hypothyroid syndrome is often atypical (formes frustes) and the average lowering of the metabolism rate is -21. 4. Lymphatic type (clinical picture of lymphatism). The lowering of the metabolism rate varies from -12 to -18.

C. Hypophyseal states. In only one case in ten was a lowering of the metabolism rate noted. It was found normal in several typical cases of mongolism and chronic encephalopathy.

Plan to Erect Statue of Laënnec in Paris

No statue of Laënnec exists at present in Paris. A committee headed by Professor Sergent has just been appointed to collect funds for a statue to be erected on a site in front

of the new laboratory buildings which replace those of the Charité hospital. The amphitheater in which Laënnec taught in the latter institution still exists and the wards in which the discoverer of auscultation first applied this method faced the square in which the proposed statue will be placed. Those who wish to subscribe can send their contribution to Dr. Doury, 4 rue de la Muette, Paris (16).

Laying of Corner Stone of Hygiene Building for 1937 Exposition

The Paris Exposition, which will open its doors on the first of May, proposes to show the progress made in all human activities, especially hygiene. The corner stone of the hygiene building was recently laid by M. Henri Sellier, minister of public health, aided among others by Professor Tanon, head of the department of hygiene at the Medical School of the University of Paris.

Annual Election of Officers of Academy of Medicine

Prof. Henri Hartmann of Paris was president of the Académie de médecine during 1936. His successor for 1937 will be Professor Martel. As vice president for 1937 and president in 1938, Professor Bezançon was elected at the annual meeting of the academy, held Dec. 22, 1936.

Decrease in Venereal Disease in German Navy

How to combat venereal diseases in the defense forces is always a difficult problem. Data on venereal infection among the men of the German fleet from 1920 to 1935 have been made public in the *Oeffentlicher Gesundheitsdienst* by Dr. Heinrich Ruge who, in addition to holding the high naval rank of squadron surgeon, is director of the hygienic section of the health bureau at the Baltic Naval Station, Kiel.

The number of venereal disease cases in the fleet has undergone a steady decline since 1924, a year that was marked by a definite subsidence of the evil effects of revolution and inflation. The incidence of all three venereal diseases diminished in equal measure. The results obtained in the fight against gonorrhea were gratifying despite the well known difficulties encountered in the suppression of this disease. The number of newly reported cases of gonorrhea amounted to 7.15 per cent in 1922; this proportion then underwent a steady decline and was only 1.67 per cent in 1934 and 1.51 per cent in 1935. The number of relapsed cases fluctuated between 1.1 per cent in 1922 and 0.2 per cent in 1934. Infections contracted in foreign ports constituted an insignificant proportion of all cases; of 3,087 gonorrheal infections reported from 1926 to 1930, 199 (6.4 per cent) were contracted abroad; in the period from 1931 to 1935 in a total of 2,023 gonorrheal infections, ninety-eight (4.8 per cent) were contracted abroad.

The incidence of syphilis cases presents a similar picture excepting that here the decline has been even more pronounced. In 1923 the percentage of newly reported cases of syphilis was 3.45, 3.9 if cases of double infection are included; in 1934 new cases of syphilis amounted to a mere 0.15 per cent and no cases of double infection were reported. The foregoing figures indicate, with regard to syphilis, that since 1924 we have been passing through the epidemiologic trough of the wave. On the other hand a slight increase in the incidence of syphilis has been observed in France, and similar increases have been noted here and there in both Germany and Italy. Moreover, the number of syphilitic infections acquired by German navy men abroad has steadily increased, such cases originating chiefly in tropical or subtropical regions. The proportion of cases of

syphilis contracted abroad was 14.4 per cent in the period from 1926 to 1930, 20.8 per cent from 1931 to 1935.

Chancroid is considered a filth disease, and under improved hygienic conditions it practically disappears. The proportion of patients presenting chancroid in 1923 was still 1 per cent, by 1924 it had already fallen to 0.3 per cent, and after 1931 it ceased to be of any numerical significance. The majority of chancroid cases (57 per cent or 163 in a total of 286 cases) were of foreign origin. In the majority of instances the infection was contracted in a brothel.

There were twenty-eight cases of climatic bubo (lymphogranuloma inguinale) reported in the fleet between 1924 and 1932.

The following were set forth as causal factors in this strikingly abrupt recession of venereal infection of all three types: decrease in venereal disease among the population as a whole, more adequate instruction and advice to the naval personnel on the subject of venereal diseases, better knowledge of the sources of infection, and improvement in prophylactic and therapeutic measures.

New cases of venereal infection reported abroad can almost without exception be traced to brothels. The introduction of routine instruction to the ships' people by the doctor was followed by an increase in the number of seronegative primary infections recorded and this is a definite indication that fewer of the men permitted precious time to elapse before reporting sick. The detection of the source of infection is extremely important. This was possible in about a third of the cases, and 75 per cent of the prostitutes involved were identified and subjected to medical examination. An average of from 60 to 70 per cent of the women examined were found to be infected and 90 per cent of those ill presented gonorrhea. Cases of double infection with syphilis and gonorrhea were seldom encountered. Reported cases in which other men were found to have transmitted venereal infections were extremely rare. Speedy and adequate prophylaxis was shown to be of decisive importance. Preventive measures are particularly necessary in parts of the world where a vast majority of the prostitutes are diseased, in seaports adjoining large cities of the tropics for example. During the years 1925-1936 approximately 27,000 prophylactic treatments were given the men of the German warships in foreign waters. These measures proved effective for all but 1.29 per cent of the men treated. It was found that the incidence of cases in which prophylaxis was ineffectual increased in proportion to the amount of time that had elapsed subsequent to sexual intercourse. The manifestation of disease could as a rule not be prevented if prophylaxis was not administered within five hours following contact. In the period from 1920 to 1923 conditions had been execrable; there was no routine administration of prophylaxis and the number of venereal infections had undergone a sharp increase. Regular prophylaxis was reinstituted in 1923 and this incontestably was responsible, in part at least, for the marked subsidence of venereal infection that has taken place since 1924. The administration of prophylactic treatment is made as nearly compulsory as possible. Prophylaxis on board ship in foreign waters is carried on with suppositories of strong protein silver and of similar silver preparations. This procedure is apparently more effective than the instillation of solutions. In addition, following the usual washing and after flushing with a mercury bichloride solution, a 0.5 per cent mercury bichloride ointment is applied; more general use of condoms by the sailors has been an especially important prophylactic factor.

Diagnosis and Treatment in Bronchial Carcinoma

Professor von Eicken, ordinarius of laryngology at Berlin, recently discussed the diagnosis and treatment of bronchial carcinoma in the Berlin Medical Society. The apparent increase in bronchial carcinoma seems to be ascribable to the fact that

diagnosis is now being established with greater frequency than in former times. Before the introduction of roentgen examinations, this particular diagnosis was scarcely ever made. Recently bronchoscopy has become an important diagnostic aid; by employing this procedure, von Eicken has been able to establish incontestable diagnoses in sixteen of twenty cases. Bronchoscopy is at the same time of great therapeutic importance in these cases, as its use makes possible mechanical removal with the scoop-forceps of carcinomatous masses which narrow the bronchus and also the placing of radium in the immediate vicinity of the carcinoma where the radioactivity will be most effective. The position of small radium containers in the bronchial tree and the studding of the cancer with radon needles are controlled through x-ray visualizations. The pulmonary region is often surprisingly well cleared up by means of this procedure. Von Eicken explains this by the disappearance of a stasis of secretion that has formed as a result of the bronchial stenosis. With the cessation of coughing the patient obtains considerable relief. Although life may be prolonged by the use of this procedure, one cannot of course expect cures to result.

In the discussion of von Eicken's report it was emphasized by the internists present that this procedure should be considered an important advance, as by its application the danger of gangrene and the formation of abscesses distal to the bronchial carcinoma may be successfully averted. Atelectasis too appears to abate in the cases so treated. Roentgen therapy is considered to hold no prospect of success in bronchial carcinoma. Early diagnosis is important. Bronchoscopic procedures of today, if properly carried on, spare the patients the torture which they formerly were forced to endure.

Advertising in the Medical Press

Although the new régime in Germany has done away with the German Medical Professional Press Association, an organization with a long standing record of efficiency, one small department, the so-called Advertisement Investigation Committee, has been permitted to carry on.

The function of this board has always been the formulation of the standards that govern the acceptance or rejection of advertising copy by the medical journals. It had accordingly been influential in excluding much undesirable material from the advertising sections of these publications. The criteria applied to proposed advertisements have lately been modified on the basis of the new governmental regulation of the entire pharmaceutical industry (*THE JOURNAL*, Aug. 22, 1936, p. 599). Advertisements of pharmaceutical novelties the composition of which is not set forth in the usual works of reference must contain a description of the effective substance that will be readily comprehended by the medical reader. In the advertisements of medicaments that cannot legally be dispensed without a prescription, as well as iodine and iodine salts, the precise content of the effective substances in question must be given. It is forbidden to solicit testimonials and recommendations of the public. Illustrated advertisements must be in keeping with the importance and serious character of the pharmaceutical industry. The commission also passes on whether or not a picture presents too great an affront to the esthetic sense. The commission is also soon to make public the names of those firms whose advertising in the medical journals is not to be recommended. It also possesses the right to forewarn the profession against the advertising of certain substances, articles, procedures and treatments.

Some years ago the Advertisement Investigation Committee drew up a list of certain types of disapproved advertisements. This list has recently been revived. These efforts to carry forward a work that has been going on for decades are in themselves most welcome.

VIENNA

(From Our Regular Correspondent)

Feb. 27, 1937.

Vital Statistics of Austrian Jews

The Central Headquarters of Jewish Congregations of Austria, located in Vienna, has just published an interesting statistical report. In 1923 there were 220,208 Jews resident within the republic of Austria (201,513 within Vienna alone). In 1934 the Jewish population was reported to number 191,481 persons, of whom 176,034 were in Vienna. The total decline here represented amounted to 13 per cent. This retrogression in the Jewish population is in direct contrast to the trend among the non-Jewish elements. First among the contributing causes is the marked falling off in the Jewish birth rate. In 1923 there were still 2,736 Jewish infants born; in 1928 the figure was 1,362, by 1933 it had fallen to 900 and in 1936 it amounted to a mere 757. The number of deaths among Austrian Jews was 2,571 in 1923, 2,669 in 1928, 2,689 in 1933 and 2,757 in 1936. A slight increase (by 162 persons) over the previous years in the Jewish population was still noted in 1923. But a progressively larger natural decline is to be observed from 1924 on. Numerically the decline progressed as follows: there were 132 fewer Jews in 1924 than in 1923, 1,307 fewer in 1928, 1,789 fewer in 1933 and 1,994 fewer in 1936. It is interesting to observe also that the number of persons leaving the Jewish community has steadily declined (from 1,276 to 534). The following causes of fatalities occurring in 1936 were reported: heart disease caused 24 per cent of all deaths, cancer 16 per cent, disease of the respiratory tract 12 per cent, diseases of the blood and vascular system (exclusive of heart disease) 17 per cent, diseases of the uropoietic system 6 per cent, marasmus 5 per cent, tuberculosis 4.5 per cent. Of Jews who died in 1936, 1,451 were of the male sex, 1,264 of the female sex. There were thirty-six stillbirths among the 757 births. Of the infants born alive, 366 were male, 355 female. There were fifty-four children born out of wedlock. The relatively large number of Jews who survive to the age of 90 is astonishing. In 1928 there were 217 Jews in Austria 90 years of age or over, and twenty-two of these persons had attained the age of 100. In 1929 there were 255 Jews aged 90 or more (of whom thirty-two were centenarians). Two years later the number of persons over the age of 90 was 266, including twenty-three persons aged 100 and three persons who were even older. Among the extremely aged the women constantly outnumbered the men by about 50 per cent. The number of these longeval persons remained virtually constant during the years following 1931. As an interesting supplement to the foregoing report on a particular element of the Austrian population, one may consider a recently published report of the Vienna Municipal Health Bureau which deals with the general condition of the Viennese population. According to this report there were 208 deaths to each hundred births in Vienna in 1936 and 215 deaths per hundred births in 1935 but only eighty-one deaths per hundred births in 1913. Altogether there were 11,945 infants born in Vienna (in 1936), but 24,869 persons died during the same year. There were 37,632 births and 30,613 deaths in 1913. The divisions according to cause of death among the Viennese population as a whole differ percentally but little from the corresponding proportions among the Jewish inhabitants (Jews constitute 10 per cent of the entire population in Vienna but they form only 3 per cent of the entire Austrian population). Exceptions are deaths from tuberculosis, which are almost twice as frequent among the non-Jewish as compared with the Jewish population; deaths from cancer are, however, 10 per cent more frequent among the Jews. The number of nonagenarians and centenarians is also relatively much smaller among the non-Jews; in other words, longevity is more conspicuous among Jews than among the population as a whole.

Presacral Procaine Hydrochloride Injections in Sciatica

Dr. Fenz reported in one of the more recent sessions of the Physicians' Society the treatment of forty cases of sciatica with presacral injections of 0.25 per cent solutions of procaine hydrochloride. This method was described two years ago by Dr. Pendl of Troppau but until now, in spite of the noteworthy results reported by Pendl, has received no verification from any other source. The procedure is simple. The patient lies supine, the legs are spread apart and the knees are propped up in a stationary position. A thin needle from 15 to 20 cm. in length is then introduced into the affected side from 1.5 to 2 cm. from the tip of the coccyx. It is next advanced, parallel to the os sacrum, within the presacral cavity till it reaches a point above the first and second sacral foramina. In this way the needle enters directly into the vicinity of the sacral roots of the nervus ischiadicus. The region is then injected with 150 cc. of a 0.25 per cent solution of procaine hydrochloride and the injection is continued while the needle is being withdrawn. The procedure is nearly always painless; in the more severe cases it is carried on under narcosis with the sodium salt of *n*-methyl-cyclo-hexenyl-methyl barbituric acid. If skilfully performed, the procedure is quite innocuous. It was employed seventy-six times by Dr. Fenz without the occurrence of the slightest accident. The intervention is not infrequently performed under circumstances of presacral anesthesia due to loss of nerve conduction. It is essential to the favorable performance of this presacral injection that a sufficient amount of the solution be deposited at the point of exit of the sacral ischiadic roots. Pendl even believes that the favorable results are to be attributed more to the large amount of fluid injected than to the anesthetic itself. The effect of the injection in Fenz's forty cases was truly remarkable; in only fourteen cases was a second injection necessary. Of the cases, 85 per cent were completely cured; the exceptions were old cases for which all other possible therapeutic procedures had been attempted unsuccessfully. Of the latter only two remained completely unresponsive; five patients were sent home manifestly improved. Follow up of the cured patients over the course of from one and a half to two years disclosed only two who were not entirely symptom free.

Centenary of Prof. Leopold Schrötter von Kristelli

The University of Vienna recently celebrated the one hundredth birthday anniversary of the Viennese physician Professor von Schrötter by the solemn unveiling of a memorial in the great courtyard on the university campus. Von Schrötter was the son of the chemist Anton von Schrötter, the discoverer of red phosphorus. Among his teachers were Hyrtl, Rokitsansky and Skoda. Von Schrötter became assistant to the last named and received from him an excellent foundation in internal medicine. At the same time von Schrötter became intensely interested in the new specialty of laryngology which Türck had founded. Von Schrötter devised many new methods of diagnosis and examination and was appointed docent in laryngology in 1867. He soon was able to secure the establishment of his own laryngologic clinic, the first of its kind in the entire world. Schrötter served as chief of this clinic (from 1870) and thereafter laryngology and rhinology also came to assume their present-day significance. Thanks to Schrötter and his successors (Schnitzler, Störk, Chiari, Hajek) Vienna became the center of laryngologic research. The rich harvest of experimental knowledge garnered in this clinic was put into book form by Schrötter himself in his two greatest publications, "Lectures on Diseases of the Larynx" and "Lectures on Diseases of the Trachea." Schrötter also originated the bouginage method for the treatment of laryngeal stenosis and the beginnings of tracheoscopy. It may be recalled that it was Schrötter

who (in 1888) correctly diagnosed the malignant affliction of the German crown prince (and later emperor) Friedrich of Germany. In addition to his activity as chief of the laryngologic clinic, Schrötter served both as director of the clinic of internal medicine (from 1872) and as head of the internal section of Rudolf Hospital. In 1890 a large special clinic of internal medicine was placed at his disposal at the General Hospital. There he conducted a series of instructive lectures, which were to become classic. These had to do in particular with diseases of the heart, vascular system and respiratory tract. Schrötter rendered a signal and fundamental service to the modern technic of hydraulic engineering by his investigations of caisson disease, a malady that made its appearance with modern industrial activities carried on under high atmospheric pressure. The most important and far reaching of Schrötter's activities were his efforts on behalf of the campaign against tuberculosis. This disease was then known and feared as the *morbus viennensis*. Schrötter was stirred by the vast extent of tuberculous infection, the havoc it wrought in the population's health and the inefficacy of contemporary therapeutics. He realized that only fresh air and sunshine, favorable climate and a hygienic dietary regimen could be of therapeutic benefit. He vigorously campaigned for the establishment of health stations in which tuberculous persons of the underprivileged classes might receive adequate care and he possessed a fanatical belief that tuberculosis might be cured at any stage, provided timely treatment could be introduced. Schrötter was actually able to effect the establishment of these tuberculosis sanatoriums. He was also the initiator and organizer of public education for the prevention of tuberculosis. By the dissemination of pamphlets for "the man in the street," by the placing of placards in workshops and factories, and by lectures which reached all classes of the population, he succeeded in convincing the general public of the value of improved hygiene in the prophylaxis of tuberculosis. Schrötter was responsible too for the international agreement with regard to all phases of the campaign, duly concluded at the International Antituberculosis Congress (Paris 1898); thus he was the originator of a veritable "league of nations" arrayed against the disease. The circumstances of Schrötter's death were tragic. At the International Congress of Rhinology, held at Vienna in 1908, he delivered the commemorative addresses in honor of Türk and Czermak, the fathers of laryngology. He was then 71 years old. That evening Schrötter entertained a throng of visitors to the congress in his home and during the night his active life was suddenly cut short by an apoplectic stroke.

Marriages

CHARLES DENBEIGH MARCHANT, Harmony Village, Va., to Miss Marian Steptoe Fitzhugh of Urbanna, January 28.

HERBERT H. HARRIS, Rockwell City, Iowa, to Sylvia J. Hoffman of Portland, Ore., Oct. 4, 1936.

THOMAS EARLE MARTIN, Guntersville, Ala., to Miss Celia Dean at Alexander City, in February.

CLARA CHRISTIE to Mr. Orrin Henry Eyres Might, both of Calgary, Alta., Canada, January 14.

ISHAM SELLERS MOORE JR., Runge, Texas, to Miss Dorothy Cronin of Houston, Dec. 31, 1936.

FREDERICK TOWSLEY MURPHY to Mrs. Frederick M. Alger, both of Detroit, in January.

EDWARD LEE HOPEWELL, Strasburg, Va., to Miss Effie Elizabeth Lively, February 14.

DWIGHT L. HOOD to Mrs. Beulah Harlie, both of Reno, Nev., Dec. 18, 1936.

THOMAS H. MILTON, Kenvir, Ky., to Miss Alice Kammeyer, in February.

FREDERICK E. ROSE to Miss Felicia Green, both of St. Louis, in January.

Deaths

Randolph Winslow ☉ Baltimore; University of Maryland School of Medicine, Baltimore, 1873; an Affiliate Fellow of the American Medical Association; member of the House of Delegates of the American Medical Association, 1905-1906, 1911, 1913, 1916-1923, 1927-1934, and member of the Judicial Council, 1915-1922; past president of the Medical and Chirurgical Faculty of Maryland and of the Baltimore City Medical Society; member and past president of the Southern Surgical Association; fellow and one of the founders of the American College of Surgeons; professor emeritus of surgery at his alma mater, professor of surgery, 1902-1920, professor of anatomy and clinical surgery, 1891-1902, lecturer of clinical surgery, 1886-1891, demonstrator of anatomy, 1880-1886, assistant demonstrator of anatomy, 1874-1880, and for many years a regent; formerly professor of surgery at the Woman's Medical College, Baltimore; first lieutenant in the medical reserve corps of the U. S. Army, 1909-1917; surgeon to the University Hospital; was awarded honorary degrees by St. John's College, Annapolis, in 1909, and the University of Maryland in 1924; aged 84; died, February 27.

Henry Benjamin Carey ☉ San Francisco; Northwestern University Medical School, Chicago, 1905; began teaching at the School of Pharmacy, Northwestern University, in 1900; in 1906 was appointed professor of botany and pharmacognosy at the California College of Pharmacy and continued in that position for thirty years; for many years acted as instructor and assistant professor in anatomy and histology in the Dental College, University of California; in 1932 he became acting dean of the California College of Pharmacy, which in 1934 became the College of Pharmacy of the University of California; aged 60; died, February 4, in the University of California Hospital, of carcinoma of the stomach.

William Cotterrell Bane ☉ Denver; Jefferson Medical College of Philadelphia, 1879; member of the American Academy of Ophthalmology and Oto-Laryngology and the American Laryngological, Rhinological and Otological Society; fellow of the American College of Surgeons; professor of otolaryngology emeritus, University of Colorado School of Medicine; member of the staff, St. Joseph's, Mercy, Presbyterian and St. Luke's hospitals; consultant, Children's Hospital; otolaryngologist to Denver Orphans' Home; consultant oculist for the Rock Island Railroad and the Denver and Rio Grande Western Railroad; aged 81; died, January 20, of coronary thrombosis.

Joseph Manning Steiner ☉ Greenville, Ala.; Tulane University of Louisiana Medical Department, New Orleans, 1904; member of the American Roentgen Ray Society and the Medical Society of the State of New York; served during the World War; director of the department of roentgenology, 1924-1932, Roosevelt Hospital; formerly on the staffs of the Doctors Hospital and the New York Infirmary for Women and Children; aged 56; died, January 27, of an injury received in a fall.

Howard Frederick Rand, Los Angeles; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1894; for many years assistant surgeon to the Battle Creek (Mich.) Sanitarium; superintendent and surgeon to the Boulder, Colo., Sanitarium and St. Helena Sanitarium and Hospital, Sanitarium, Calif.; surgeon to the Glendale (Calif.) Sanitarium and Hospital; aged 77; was killed when struck by an automobile, January 22.

Samuel Wakelin Worrell, Patton, Pa.; University of Buffalo School of Medicine, 1892; member of the Medical Society of the State of Pennsylvania; for nearly twenty-five years local registrar of vital statistics, state health department; health officer of Patton Borough and East Carroll Township for many years; aged 76; died, January 22, in the Windber (Pa.) Hospital, of carcinoma of the esophagus.

Laurence Donald McEvoy, New York; Missouri Medical College, St. Louis, 1896; member of the Medical Society of the State of New York; veteran of the Spanish-American and World wars; aged 70; died, January 29, in the Mount Sinai Hospital, of suppurative bronchopneumonia and coronary thrombosis.

Thomas William Moffitt, Los Angeles; Starling Medical College, Columbus, 1893; member of the California Medical Association; fellow of the American College of Surgeons; on the staff of the Hollywood Hospital; consulting surgeon to the Soldiers' National Home, Sawtelle; aged 66; died, January 4.

Wilbur Fisk Martin ☉ Colorado Springs, Colo.; College of Physicians and Surgeons, Medical Department of Columbia

College, New York, 1887; on the staff of the Beth-El Hospital and on the visiting staff of the Glockner Sanatorium and Hospital; aged 73; died, January 16, of influenza and pneumonia.

Morris Meyerovitz, Chicago; College of Physicians and Surgeons of Chicago, 1890; formerly member of the Illinois State Board of Health and the Chicago Plan Commission; at one time on the staff of the Cook County Hospital; aged 76; died, March 3, of coronary thrombosis and arteriosclerosis.

Clyde Talbot Bundy * Earl Park, Ind.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1909; served during the World War; aged 52; died, February 18, in St. Elizabeth Hospital, Lafayette, of ischiorectal abscess and pulmonary tuberculosis.

Bethune Freeman McDonald, Palestine, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1916; member of the State Medical Association of Texas; attending physician to the Missouri Pacific Lines Hospital; aged 44; died, January 23, of coronary occlusion.

Charles Sidney Walker * Keene, N. H.; Dartmouth Medical School, Hanover, 1901; past president of the New Hampshire Medical Society; served during the World War; city physician; on the staff of the Elliott Community Hospital; aged 66; died, January 19, of pneumonia.

Earl Vincent Morrow, Portland, Ore.; University of Oregon Medical School, Portland, 1910; was decorated by Belgium, France and America for services during the World War; aged 52; died, January 28, in the Virginia Mason Hospital, Seattle, of coronary thrombosis.

Charles Kincaid Summers, Nashville, Tenn.; Memphis Hospital Medical College, 1899; served during the World War; formerly assistant superintendent of the Central State Hospital; aged 58; died, January 25, in the Veterans Administration Facility, Memphis, of pneumonia.

Henry George Mauzey, Walla Walla, Wash.; Bellevue Hospital Medical College, New York, 1870; member of the Washington State Medical Association; was commissioned in the army in 1870; aged 88; died, January 31, in St. Mary's Hospital, of bronchopneumonia.

Albert A. Lowenthal, Chicago; College of Physicians and Surgeons of Chicago, 1895; at one time adjunct professor on mental diseases at his alma mater; formerly on the staff of the Cook County Hospital; aged 63; died, March 19, of coronary occlusion and diabetes mellitus.

Samuel W. Maphis, Warrenton, Va.; University of Maryland School of Medicine, Baltimore, 1893; member of the school board; for many years member of the state board of medical examiners; aged 69; died, January 26, of heart disease in Panama, Canal Zone.

Alexander Fitzhugh Magruder * Surgeon Lieutenant Commander, U. S. Navy, retired, Washington, D. C.; Columbian College Medical Department, Washington, 1871; entered the navy in 1871 and retired in 1896; aged 87; died, January 27, of pneumonia.

Charles Oliver Woodbridge, Saline, Mich.; Detroit College of Medicine, 1904; member of the Michigan State Medical Society; member of the city council; aged 56; died, January 24, in the University Hospital, Ann Arbor, of carcinoma of the stomach.

J. Russell Van Sickle, Santa Monica, Calif.; Detroit College of Medicine, 1906; member of the California Medical Association; on the staff of the Wilshire Hospital; aged 56; died, January 16, of coronary occlusion and diabetes mellitus.

William Pitt Mason, Little Boars Head, N. H.; Albany (N. Y.) Medical College, 1881; member of the Medical Society of the State of New York; aged 83; died, January 25, in North Hampton, of cerebral hemorrhage and cerebral sclerosis.

Silas Alfred McCullough, Pomeroy, Ohio; Starling Medical College, Columbus, 1904; member of the Ohio State Medical Association; county probate judge; formerly county health officer; aged 59; died, January 21, of pneumonia.

Edward Townsend McKenzie, New York; Columbia University College of Physicians and Surgeons, New York, 1901; member of the Medical Society of the State of New York; aged 64; died, January 28, in the Presbyterian Hospital.

Charles Fleetwood House, Walters, Okla.; Tulane University of Louisiana Medical Department, New Orleans, 1901; member of the Oklahoma State Medical Association; aged 64; died, January 8, in a hospital at Wichita Falls, Texas.

Walter Dora Lenker * San Bernardino, Calif.; College of Medical Evangelists, Los Angeles, 1918; at one time city and county health officer; formerly superintendent of the San Bernardino General Hospital; aged 43; died, January 30.

Alexander Beaton Chalmers, Fort Erie North, Ont., Canada; L.F.P.S. Glasgow, Scotland, 1880; M.B., C.M., University of Glasgow Medical Faculty, Scotland, 1881; aged 78; died, January 8, in the Douglas Memorial Hospital.

Archibald Joseph Kilgour, Kingston, Ont., Canada; University of Toronto Faculty of Medicine, 1922; member of the American Psychiatric Association; medical superintendent of the Ontario Hospital; aged 44; died, January 28.

H. Nelson Heffin * Kewanee, Ill.; Minneapolis College of Physicians and Surgeons, 1895; formerly health officer of Kewanee; on the staffs of the Kewanee Public Hospital and St. Francis Hospital; aged 72; died, January 15.

Horace Lindsley, St. Augustine, Fla.; Hahnemann Medical College of Philadelphia, 1887; formerly bank president and member of the county board of education; aged 81; died, January 21, of carcinoma of the descending colon.

Matthew Vassar Pierce * Milton, Mass.; Harvard University Medical School, Boston, 1880; formerly on the staff of the Milton Hospital and Convalescent Home; aged 81; died suddenly, January 24, of coronary thrombosis.

William F. Reilly, Cincinnati; Southern Homeopathic Medical College, Baltimore, 1895; formerly professor of rhinology and laryngology, Pulte Medical College; aged 80; died, January 5, in the Good Samaritan Hospital.

Philip Graham Reedy, Lisbon, N. D.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1910; served during the World War; aged 54; died, Dec. 19, 1936, in Fargo.

John Parks Gilmer, Los Angeles; Kentucky School of Medicine, Louisville, 1899; formerly police surgeon; served during the World War; aged 60; died, January 25, of peritonitis following a ruptured appendix.

Harry Stanley Lake * Brightwood, Bethel Township, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1899; veteran of the Spanish-American and World wars; aged 64; died, January 3, of lobar pneumonia.

Edgar Lawrence Ingersoll * Ephrata, Wash.; University and Bellevue Hospital Medical College, New York, 1899; served during the World War; county health officer; aged 64; died, January 28, in Spokane.

George Ellisworth Sutton, San Francisco; University of Minnesota Medical School, Minneapolis, 1914; served during the World War; fellow of the American College of Surgeons; aged 50; died, January 31.

Robert Wilson Barton, Temple, Texas; Louisville (Ky.) Medical College, 1880; one of the founders and for many years on the staff of the King's Daughters' Clinic and Hospital; aged 80; died, Dec. 27, 1936.

William Alexander Chisholm Macdonald, Windsor, Ont., Canada; University of Toronto Faculty of Medicine, 1899; served with the Canadian Army during the World War; aged 61; died, January 24.

Charles S. McDevitt, Des Moines, Iowa; University of Louisville (Ky.) Medical Department, 1909; aged 56; died, January 24, in the Mercy Hospital, of lobar pneumonia and intestinal obstruction.

Le Roy H. Daggett, Chicago; Jenner Medical College, Chicago, 1900; member of the Illinois State Medical Society; aged 64; died, February 3, in the Highland Park (Ill.) Hospital, of pneumonia.

George Alexander McQuibban, Alma, Ont., Canada; University of Toronto Faculty of Medicine, 1911; member of the Ontario Legislature for Wellington North since 1926; aged 52; died, January 30.

James Edward Copeland, Round Hill, Va.; Washington University School of Medicine, Baltimore, 1876; member of the Medical Society of Virginia; Confederate veteran; aged 91; died, January 17.

Leonard C. Ward, Damascus, Ga.; Atlanta College of Physicians and Surgeons, 1899; member of the Medical Association of Georgia; aged 60; died, January 31, in Bainbridge, of heart disease.

Edward Larned McGehee Jr., Hammond, La.; Tulane University of Louisiana Medical Department, New Orleans, 1902; aged 57; died, January 30, of hypertensive heart disease and nephritis.

John Franklin Harvey, Boston; University of the City of New York Medical Department, 1890; aged 79; died, January 16, in the City Hospital, of uremia and hypertrophy of the prostate.

Levi M. McFadden, Washington C. H., Ohio; University of Louisville (Ky.) Medical Department, 1892; for many years a member of the state legislature; aged 68; died, January 11, in Orrville.

Silas Wilkin Weir @ West Union, Ill.; St. Louis College of Physicians and Surgeons, 1906; aged 57; died, January 30, in the Union Hospital, Terre Haute, Ind., of acute dilatation of the heart.

Frank Dumont Sweet, Long Beach, Calif.; Atlanta Medical College, 1916; member of the California Medical Association; aged 49; died, January 24, as the result of an automobile accident.

Abraham Lincoln Shope, Penbrook, Pa.; Jefferson Medical College of Philadelphia, 1890; for many years a member of the Penbrook borough council; aged 68; was found dead, January 10.

Joseph Henry Carroll, Columbus, Ohio; Western Reserve University Medical Department, Cleveland, 1894; served during the Spanish-American War; aged 66; died, January 5, in Dayton.

Robert Mark Lees, Kenosha, Wis.; Marquette University School of Medicine, Milwaukee, 1933; aged 28; died, January 27, at a Civilian Conservation Corps camp near Grand Canyon, Ariz.

Walter George Finley, San Fernando, Calif.; John A. Creighton Medical College, Omaha, 1903; pathologist to the Veterans Administration Facility; aged 57; died, January 29.

James Albert Darby, Vancouver, Wash.; University of Oregon Medical School, Portland, 1909; member of the Washington State Medical Association; aged 62; died, January 18.

George Campbell Speirs, Philadelphia; Medico-Chirurgical College of Philadelphia, 1898; also a dentist; aged 66; died, January 30, in Atlantic City, N. J., of coronary insufficiency.

Francis Percival Fitzpatrick, Campbell, Ohio; Georgetown University School of Medicine, Washington, D. C., 1913; served during the World War; aged 49; died, January 23.

Fred C. Wiley, Pigeon, Mich.; Detroit College of Medicine, 1896; on the staff of the Hubbard Memorial Hospital, Bad Axe; aged 64; died, January 21, of cerebral hemorrhage.

Albert Frank Zimmermann, Los Angeles; University of Southern California College of Medicine, Los Angeles, 1905; aged 65; died, January 21, of a self inflicted bullet wound.

Joseph Grant Bartow, Lansing, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1891; aged 73; died, February 20, of coronary sclerosis.

John Bommer, Midnight, Miss.; Vanderbilt University School of Medicine, Nashville, Tenn., 1886; aged 94; died, January 30, in the King's Daughters' Hospital, Yazoo.

Arell La Fayette Marsteller @ Wilcox, Neb.; Barnes Medical College, St. Louis, 1906; past president of the Kearney County Medical Society; aged 54; died, January 24.

John F. McCool @ Indianapolis; Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1906; aged 52; died, January 21, in St. Vincent's Hospital.

Benjamin Duncan Morrison, Wheeling, W. Va.; Hahnemann Medical College of Philadelphia, 1888; aged 72; died, January 25, in Beech Bottom, of diabetes mellitus.

John Paul Hoeffer @ St. Louis; Washington University School of Medicine, St. Louis, 1892; aged 69; died, January 24, in Webster Groves, Mo., of coronary occlusion.

Stanley H. Steiner @ New York; Columbia University College of Physicians and Surgeons, New York, 1909; aged 52; died, January 24, of cerebral hemorrhage.

Duncan M. Wood, Needham, Mass.; McGill University Faculty of Medicine, Montreal, Que., 1895; aged 69; died, January 27, in the Glover Memorial Hospital.

Samuel George Boyd, San Francisco; Harvard University Medical School, Boston, 1885; member of the Massachusetts Medical Society; aged 75; died, January 23.

Clayton A. Tribbet @ Westboro, Ohio; Miami Medical College, Cincinnati, 1886; past president of the Clinton County Medical Society; aged 82; died, January 5.

David Coyle McCulloch, Los Angeles; Medico-Chirurgical College of Philadelphia, 1896; served during the World War; aged 72; died, January 17, of tuberculosis.

Gustavus M. Wallace, Falmouth, Va.; University of Maryland School of Medicine, Baltimore, 1871; state senator; aged 88; died suddenly, January 28, of senility.

Robert L. Cherry, Bardstown, Ky.; Louisville National Medical College, Medical Department State University, 1902; also a minister; aged 76; died, January 2.

George Hoitt Sanborn @ Henniker, N. H.; Medical School of Maine, Portland, 1874; aged 82; died, January 23, of pulmonary infarct and coronary thrombosis.

Thomas Hughes @ Chicago; Northwestern University Medical School, Chicago, 1892; aged 70; died, February 5, of bronchopneumonia and diabetes mellitus.

Williams Davis Wall Jr., Zachary, La.; Tulane University of Louisiana Medical Department, New Orleans, 1893; aged 66; died, January 6, of angina pectoris.

William B. Shields, St. Louis; Memphis (Tenn.) Hospital Medical College, 1889; aged 73; died, January 22, in the Missouri Baptist Hospital, of pneumonia.

William T. Morrison, Pigeon, Mich.; Michigan College of Medicine and Surgery, Detroit, 1896; aged 71; died, January 31, of carcinoma of the stomach.

John Henry Sylvester O'Brien, Pittsfield, Mass.; Long Island College Hospital, Brooklyn, 1899; aged 71; died, January 8, in St. Luke's Hospital.

Olaf I. Refsdahl, Hayfield, Minn.; Northwestern University Medical School, Chicago, 1910; aged 58; died, January 14, in Austin of myocarditis.

Emanuel D. Block, Webster Groves, Mo.; St. Louis Medical College, 1878; aged 81; died, January 19, of chronic myocarditis and arteriosclerosis.

Reginald Eugene Sproston Challener, Toronto, Ont., Canada; University of Toronto Faculty of Medicine, 1924; aged 36; died, January 21.

Clarence Eugene Howland, North Dartmouth, Mass.; New York University Medical College, 1897; aged 61; died, January 20, in Fall River.

Charles S. Parker, Baltimore; College of Physicians and Surgeons, Baltimore, 1881; aged 79; died, January 25, of chronic myocarditis.

James Maully Brown, McCormick, S. C.; University of the South Medical Department, Sewanee, Tenn., 1899; aged 59; died, January 11.

John D. Malott, Converse, Ind.; Medical College of Indiana, Indianapolis, 1898; aged 65; died, February 2, of cerebral hemorrhage.

Martin T. Ploughe, Kempton, Ind.; Central College of Physicians and Surgeons, Indianapolis, 1898; aged 75; died, January 18.

David Armstrong @ Durant, Okla.; St. Louis College of Physicians and Surgeons, 1914; aged 59; died, January 28, of pneumonia.

Zeno Burt Babbitt, St. Petersburg, Fla.; Hahnemann Medical College of Philadelphia, 1890; aged 75; died, February 3.

Edward F. Harpel, Shamokin, Pa.; Hahnemann Medical College of Philadelphia, 1892; aged 67; was found dead, January 21.

Frederick Smith Park, Merion Station, Pa.; Medico-Chirurgical College of Philadelphia, 1909; aged 54; died, January 20.

Lorenzo Chapman, Grand Falls, N. B., Canada; Harvard University Medical School, Boston, 1893; aged 65; died, January 5.

George Daniel Lynch, Moravia, Iowa; Barnes Medical College, St. Louis, 1899; aged 64; died, January 21, of heart disease.

Alexander Forin, Edmonton, Alta., Canada; Queen's University Faculty of Medicine, Kingston, Ont., 1884; died, January 2.

Emanuel Stockberger, Milford, Ind. (licensed in Indiana in 1897); aged 84; died, January 24, of rheumatic heart disease.

James Clark Smith Akerly, Decoto, Calif.; Cooper Medical College, San Francisco, 1885; aged 76; died, January 17.

John Walter Key, Los Angeles; College of Physicians and Surgeons of San Francisco, 1901; aged 56; died, January 31.

John Reginald Jarvis @ Buffalo; University of Buffalo School of Medicine, 1928; aged 31; died, January 17.

William B. Stokes, Belton, Texas; Memphis (Tenn.) Hospital Medical College, 1904; aged 60; died, January 5.

Wilson Montgomery, Embro, Ont., Canada; Trinity Medical College, Toronto, 1891; aged 80; died, January 7.

Emma Augusta Kalbfleisch, Boston; Boston University School of Medicine, 1887; died, January 31.

Charles A. Boyd, San Jose, Calif.; Rush Medical College, Chicago, 1881; aged 82; died, January 30.

Bureau of Investigation

RATS—AND VITAMIN F(?) IN COSMETOLOGY

Rodents Make Supreme Sacrifice to Aid A. J. Pacini and Imogene Shepherd

Of late the daily life of the white rat (*Mus norvegicus-albinus*) has certainly been made less monotonous. Great grandfather rats, tough and battle scarred from numerous conflicts with lethal diseases, are sniffing with scientific disdain while great granddaughter rats undergo nutritional deficiency tests in the cause of beauty. Silky tails are being tailcured and hides assume a new sleekness. If the ladies of the species could speak we should no doubt see their pictures with their testimonials!

In an eight-page brochure published by the "Pharmaceutical Specialties Company, a division of Archer-Daniels-Midland Company," Mary Imogene Shepherd, Ph.G., says that "It is now definitely established that the complete removal of certain indispensable unsaturated fatty acids from the diet results in the appearance of 'deficiency' symptoms which involve: 1—the skin and epidermal appendages; 2—the endocrine glands; 3—certain of the viscera, in particular the kidneys; 4—the general state of nutrition; 5—and possibly the constitutional physiology that permits allergic susceptibility to take place."

Mr. August J. Pacini, of whom on various occasions mention has been made in these columns, states in the preface to the Shepherd contribution: "I am totally unaware of the existence anywhere of a cosmetic chemist that has experimented as widely as has Miss Mary Imogene Shepherd in the matter of evaluating vitamin F's place in cosmetic preparations." This unawareness on his part is perhaps explained by the fact that Miss Shepherd is the "Managing Director and Chief Chemist of the Powder Box," a "beauty shoppe" in the Charles A. Stevens & Company store, Chicago; moreover, if you visit the Seymour Building, 155 East Ohio Street, Chicago, you will find the following concerns and individuals listed for the fourth floor: Color Cosmetics, Edward M. Johnson, Ruth Nelson, Pacini Laboratories, Inc., Dr. A. J. Pacini, Pharmaceutical Specialties Company, Imogene Shepherd, Ltd., and F. R. Warner Products Company. It has been learned from a recent commercial report that the Warner concern discontinued business about a year ago and its activities were said to have been taken over by the Pacini Laboratories, Inc.

If you take the elevator to the fourth floor, you step directly into one office, there being no hall, and as no room numbers are given in the building directory, it seems evident that the occupants of the fourth floor may be closely associated.

Miss Shepherd is not the first young woman to announce unusual properties attributable to vitamin F. The Chicago *Herald and Examiner* of March 15, 1935, stated that a Miss Mildred Oncken had "... found she could prevent rats' 'snuffles' with vitamin F ..." Miss Oncken was working in the Pacini Laboratories, Inc., at 155 East Ohio Street at the time. Much of her work has had exposition in the *Illinois Medical Journal*. In the May 4, 1935, issue of the Chicago *Herald and Examiner* Dr. A. J. Pacini was credited with the statement that "Sex can, to a certain extent, be made to order if parents desiring a boy add quantities of vitamin E to an otherwise balanced diet ..." The evidence was said to be based on 7,000 rat experiments. What a jolly time rats must have in the interest of science!

Because of the extensive advertising campaign that has been carried on by the Pharmaceutical Specialties Company in the exploitation of vitamin F, much of which appears over the signature of August J. Pacini, the Bureau of Investigation has received many requests for information relative to Pacini.

In 1925 Pacini was giving a "practical course in standardized physiotherapy" and was the Director of the Biophysical Research Department of the Victor X-Ray Corporation of Chicago. The pamphlet that carried the announcement and prospectus of the course reproduced the likeness of A. J. Pacini with the suffix M.D. following the name.

In THE JOURNAL for Sept. 19, 1925, an article appeared on the "American Association for Medico-Physical Research." In

this article reference was made to A. J. Pacini, "M.D.," and to the fact that a most careful search had failed to disclose that any one of this name was ever graduated by a reputable medical college in the United States or was licensed to practice medicine in any state in the Union. After the article appeared in THE JOURNAL, Mr. Pacini wrote that, as he could not at that time disclose the history of his alleged graduation in medicine, he would discontinue the use of the suffix "M.D." From time to time it has been found impossible by various people to verify his various statements as to his undergraduate or his scientific education.

Ten years ago any expert in nutrition would have told you that the vitamins were five in number and were lettered—A, B, C, D and E. Today there are approximately twenty-five chemically different substances which have a vitamin effect. Many of these compounds have been chemically identified and some have been synthesized. The tendency of scientists is in the direction of naming these substances according to their chemical composition, but at the present time the name "vitamin" and the designation by letter is still commonly used. From the standpoint of human nutrition, the principal vitamins may be designated A, B or preferably B₁, C, or cevitamic acid, D, E and G, which recent reports have shown to be a mixture of factors.

The omission of F from the list of vitamins has an interesting history. When the Committee on Nomenclature of the American Society of Biological Chemists met a few years ago, it was chiefly concerned with the designation of the then newly discovered fractions of the vitamin B complex. Prof. H. C. Sherman of Columbia University suggested that the two best known components of the vitamin B complex might be called vitamins F and G. The committee retained the term vitamin G, but for the substance which Dr. Sherman called vitamin F it used the designation vitamin B. Latterly vitamin B has been referred to as vitamin B₁, which is the British name for this factor. There was thus no substance designated by recognized scientific organizations as vitamin F.

In 1928 Profs. H. M. Evans and G. O. Burr at the University of California reported some experiments on the beneficial effect of fat in the diet of the rat. They said, "The favorable substance in fats—possibly a new Vitamine (F)—unlike Vitamines A, D and E is not concentrated in the non-saponifiable fraction. It can be recognized in the fatty acid portion after saponification." In 1929 Dr. Burr, then at the University of Minnesota, reported a paper entitled "A New Deficiency Disease Produced by the Rigid Exclusion of Fat from the Diet." Rats fed on mixtures of isolated food substances carefully treated so as to extract all fat did not grow normally. In addition, many of the animals developed an abnormal condition of the skin, and a peculiar scaly condition of the tail which has been referred to as caudal necrosis. Other experiments confirming the importance of fat in the diet of the rat were reported by Drs. Ava Josephine McAmis, William E. Anderson and L. B. Mendel of Yale University. Burr showed later that certain fats were better than others. The most potent were those which contain a relatively high proportion of certain unsaturated or "essential" fatty acids. Linoleic acid was effective in minute traces. Practically all students of nutrition refer to the dietary factor described by Burr as the essential fatty acids and not as vitamin F.

Undisturbed by the fact that there is no substance properly known as vitamin F, certain commercial exploiters who are interested in trade and in science seized their opportunity. The scientists may not have had vitamin F, but the exploiters did.

From this brief discussion of the subject, it does seem that certain unsaturated fatty acids, such as linoleic acid, are essential to the diet of the rat, which, no doubt, is highly important to such rodent prima donnas as Mickey and Minnie Mouse. However, the ordinary householder need have no cause for alarm; the average larder contains sufficient quantities of unsaturated fatty acid to prevent such symptoms as scaliness of the skin, inflammation of the tip of the tail, dandruff, alopecia, irregular ovulation in the females and failure to mate in the males in the ordinary brown rat (*Mus decumanus*). Anyway, if the rats can't eat what's in the house, they should go hungry.

Correspondence

NECROSPERMIA AND VIABILITY OF SPERMATOZOA IN THE CERVICAL CANAL

To the Editor:—In his letter in *THE JOURNAL*, Nov. 7, 1936, page 1581, Dr. Max Huhner disagrees with certain observations reported by me in an article on "Duration of Sperm Cell Migration in the Uterine Secretions" in *THE JOURNAL*, June 27, 1936, page 2221. He supports an opinion given by him in 1921 to the effect that demonstration of living sperm cells in the cervical canal is a more accurate evaluation of male fertility than the examination of the direct condom specimen.

I desire to stress the important fact that an unfavorable appraisal of the husband's fertility, based solely on deficient motility or complete necrospERMIA, should never be made from a condom specimen. This statement is supported by ample evidence that the chemical constituents of certain condoms are deleterious to the semen in varying degrees and may impair or suspend sperm activity within a few moments. This condition is not applicable to all condoms, but greatly reduced or completely suspended sperm cell activity in a specimen otherwise presenting normal indexes of spermatogenesis should at once arouse suspicion of error in the technic of collection. The adverse influence of the condom and overheating by unnecessary efforts to preserve the warmth of the specimen are the most common explanations.

I am confident that the foregoing statement will be found explanatory of the conflicting observations made by one or more physicians on different occasions relative to specimen activity. I wish to take this opportunity to correct a statement in an article of which I was a co-author with Dr. Hotchkiss (Semen Appraisal, *THE JOURNAL*, Feb. 24, 1934, p. 587) in which three methods of collecting the semen specimen were mentioned, the condom after cleansing being included as the third and least desirable method. At about the time the paper was published, further research had caused us to eliminate completely the use of the condom. A compromise method involving the transfer of the specimen from the condom to a glass container was also tried and abandoned because the harmful effects of the former were so rapid in occasional instances.

I wish to state that none of my observations were made from condom specimens. Unless a standardized type of condom, proved to be harmless to the semen, is habitually used, specimens so collected may give conflicting results when compared with postcoital studies and, in my opinion, are of little scientific value.

WILLIAM H. CARY, M.D., New York.

ACETARSONE IN CONGENITAL SYPHILIS

To the Editor:—The controversy between Dr. H. N. Cole and Dr. Alfred S. Traisman (*THE JOURNAL*, March 6) as to the use of acetarsone in the treatment of congenital syphilis is important. I have treated syphilis in a large children's syphilis clinic since 1924 and have used neoarsphenamine and mercury, later sulfarsphenamine and mercury and bismuth therapy, and since March 1930 stovarsol, or acetarsone. During this period at the Children's Memorial Hospital we have treated approaching 300 cases and have had no fatality nor serious reaction from this drug. The therapeutic results are at least as good as those of the older methods.

Dr. Cole mentions the article of Maxwell and Glaser in which they treated twenty-one cases and had a death in one patient and a severe toxemia in another. Maxwell and Glaser followed a system of dosage by Tuscherer, which gave no consideration to age and weight. A baby of 8½ pounds (3.8 Kg.)

was given a dosage equal to that of a child of 10 years. For example, in case 1 a baby of 8½ pounds was given a maximum of 0.75 Gm. daily. The maximum used by Traisman, Rambar, Coppolino and many others who have worked with this drug would be 0.08 Gm. daily. That is, the Tuscherer dosage is about nine times as large as the dosage in general use.

I write because it would be very unfortunate to have such a valuable drug fall by the wayside.

HAROLD A. ROSENBAUM, M.D., Chicago.

Associate in Pediatrics, Northwestern University Medical School; Member of Medical Staff, Children's Memorial Hospital.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

TUBERCULIN TEST—X-RAY EVIDENCES OF TUBERCULOSIS

To the Editor:—Will you please give the present status of a tuberculin test: The number of tests and the amount of tuberculin necessary accepted as establishing a negative. The meaning of a positive test in a patient negative clinically. The meaning of x-ray observations characteristic of past tuberculous infection in a child of 7 with repeated negative tuberculin tests. Please omit name.

M.D., Missouri.

ANSWER.—The original method of administering tuberculin as practiced by Koch was through a hypodermic needle into the subcutaneous tissues. Large doses were employed and in addition to a local reaction the physician carefully recorded any constitutional reaction, such as elevation of temperature. If there was a suspected lesion near the surface of the body, such as a cervical lymph node, one also watched for a focal reaction manifested by enlargement of the involved part, as well as tenderness. After the advent of the x-rays, suspected lesions in the lung were observed by serial films following the administration of tuberculin to determine whether there was any change in the appearance of the shadow. It was soon learned that the amount of tuberculin used in the subcutaneous test was too large and was capable of doing harm through the reactivation of lesions that were previously nonprogressive.

In 1907 Pirquet presented the epidermal test, which consisted of applying tuberculin to a small superficial scarification of the skin. By this method of administration not enough tuberculin was absorbed to produce a constitutional or focal reaction. However, a local reaction manifested by induration and hyperemia at and around the site of the tuberculin administration was good evidence of sensitization of the tissues to tuberculo-protein. Obviously, there was no measure of the dosage by this method, the scarification was not always produced to the same degree, and there was the possibility of the tuberculin being removed before a sufficient amount was absorbed to produce a reaction.

Numerous modifications of the epidermal test have been devised, such as the Moro test, which consisted of applying tuberculin to the surface of the skin without producing a scarification. This test has been perfected and described by Beatrice R. Lovett (The Percutaneous Tuberculin Reaction, *Am. J. Dis. Child.* 37:918 [May] 1929), who cleanses the skin with ether in order to remove the oil from the pores. A special preparation of tuberculin is then rubbed into the pores. When carefully performed, this test is as accurate as the Pirquet test. The reaction consists of papules scattered about the area and, in cases of high degree of allergy, folliculitis, with small vesicles or pustules and intense inflammation of the skin appear. Various tuberculin ointments are now available for this test.

More recently Ernst Wolff (*Am. Rev. Tuberc.* 27:308 [March] 1933) has described the tape test. After the skin has been carefully cleansed, a drop of tuberculin ointment the size of a pea is applied over the right side of the cleansed area, and over the left side a drop of control ointment is used. Both drops are then covered with pieces of adhesive tape 2 inches square. In forty-eight hours the tape is soaked with benzene and removed. Ten minutes later the reaction is observed. If

positive, the area over which the tuberculin ointment was applied shows papules, erythema and induration. Wolff finds that this test is generally comparable in results with the intracutaneous test of Mantoux in a dilution of 1:100.

In 1908 Mantoux presented the intracutaneous test, which consists of administering tuberculin of known strength in measured amount into the layers of the skin. This test gives one the advantage of administering an extremely small amount of tuberculin and if the tissues do not react the dose can be gradually increased. However, experience has shown that it is not necessary to begin with such small doses of tuberculin as Mantoux recommended. Although the epidermal tests, such as those presented by Pirquet, Moro and Wolff, are satisfactory when carefully administered, the intracutaneous test of Mantoux has gained favor among physicians until at present it is looked on as the standard method of administering the tuberculin test. Old tuberculin was for a long time the chief testing material, although it was known that it was only the protein content which produced the reaction. The amount of carbohydrates and other substances were so small that no harm could be produced by them. More recently Long and Seibert have prepared tuberculinoprotein in pure form, and their preparation is known as pure protein derivative. This is administered by the Mantoux method in the same manner as old tuberculin except for the difference in dosage. When one uses old tuberculin the usual procedure is to administer 0.01 mg. as the initial dose. This consists of 0.1 cc. of a dilution of 1:10,000. If no reaction occurs in from forty-eight to seventy-two hours, a second dose is given consisting of 1 mg. (0.1 cc. of a dilution of 1:100). If there is no reaction to this amount of tuberculin the individual being tested is usually thought to be free from foci of tubercle bacilli. Some workers prefer to use as the initial dose 0.1 mg. of tuberculin (1:1,000) and repeat the tests that show no reaction with 1 mg. Others employ 0.1 mg. as the only dose. A few workers have found a single dose test consisting of 1 mg. satisfactory. When one uses pure protein derivative, two tests are administered and the dosage for each test is indicated on the package. A good many workers are employing a single test dose of old tuberculin because of the large amount of work necessary in administering two tests for those negative to the first test. For example, if 100,000 persons are to be tested and only 10 per cent react positively to the first test, the remaining 90,000 must be retested. In fact, the work is almost doubled. Long is about to announce a single test dose of pure protein derivative which should save a great deal of time in the testing of large numbers of persons. Moreover, pure protein derivative is standardized so that its potency is the same whenever and wherever it is used. This statement cannot always be made concerning old tuberculin.

A positive tuberculin test has only one meaning; that is, the tissues have been sensitized to tuberculinoprotein. So far as is known there is nothing in nature ordinarily taken into the human body capable of sensitizing the tissues in this manner except tubercle bacilli which are forming or have formed tubercles. Therefore, a positive tuberculin reaction means that tubercle bacilli have entered the body through direct or indirect contact on the part of the infected individual with some person or animal suffering from tuberculosis or acting as a carrier and spreader of tubercle bacilli. Therefore a positive tuberculin reaction indicates the presence of a primary tuberculosis complex somewhere in the body.

This statement has been objected to on the ground that only 3 to 25 per cent of positive tuberculin reactors show evidence of the disease on x-ray films made of the chest. The answer to the objection is that an x-ray film of the chest includes only a small part of the human body. Not even all the lung is clearly visualized in this manner. The examination is indirect and brings to light only macroscopic lesions. In the lung hilus region it is often impossible to differentiate macroscopic tuberculous lesions from the shadows of normal structures. Indeed, it is only when sizable deposits of calcium have been laid down in the lesion that the x-ray film is of value in detecting areas of disease in this region.

A positive tuberculin reaction in a person negative clinically is usually found when only the primary complex is present. Indeed, there usually are no clinical manifestations from this form of tuberculosis except in a few persons whether they are infants, children or adults. About the time the tissues become highly allergic, there may be an elevation of temperature, lasting for a few days or a few weeks. The red cell sedimentation rate is definitely increased, but ordinarily the symptoms are not sufficient if present at all to lead the individual or close associates to believe that anything more than an acute cold or a mild attack of grip has developed and hence the physician is rarely consulted. Following these mild symptoms,

which are by no means present in all cases, the patient has the same sense of well being as the person who has not developed the primary complex.

No matter how well the positive tuberculin reactor may appear, he is likely to carry in the lesions of the primary complex living and virulent tubercle bacilli for many years and often for the remainder of his life. Moreover, his tissues are allergic to tuberculinoprotein and if tubercle bacilli in sufficient numbers at some subsequent time escape from the lesions of the primary complex or bacilli from exogenous sources reach the body and find lodgment on the allergic tissues, an intense reaction occurs which not infrequently results in necrosis of the tissues, and a destructive, symptom-producing and even fatal form of tuberculosis develops. This is true no matter where the bacilli of reinfection (from both endogenous and exogenous sources) find lodgment; if in the subarachnoid space, meningitis; if in the blood stream, miliary disease; if into the pleural space, tuberculous pleurisy, usually with effusion; if into the peritoneal cavity, tuberculous peritonitis; if in the lung or kidney, pulmonary or renal tuberculosis develop; and so on. Thus, the person who reacts positively to the test and is clinically negative today may in two or three months be dead of an acute form of tuberculosis, such as meningitis, which does not exist today. Again, the person who reacts positively to tuberculin and is negative clinically may in one to five years have serious, chronic, pulmonary or renal tuberculosis that does not exist today.

Unfortunately, after the primary complex is permitted to develop the medical profession has no specific method of holding it under control. There is no drug or mechanical procedure that destroys the bacilli or decreases the allergy of the tissues that has been found of practical value. The consoling fact is that approximately 80 per cent of positive reactors who are negative clinically do not develop reinfection forms of tuberculosis. However, evidence has accrued to show that approximately 20 per cent do present manifestations of clinical disease at some subsequent time. Unfortunately there is no method of determining whether the person with the positive tuberculin reaction who is negative clinically will fall into the 80 per cent or the 20 per cent group; therefore the only safe procedure is to examine periodically each positive tuberculin reactor, no matter how well he appears or in what age period of life. If tuberculous meningitis or miliary disease develops there is nothing the physician can do to save the patient's life in most cases. However, if one of the chronic forms of disease makes its appearance, the physician is able to detect the presence of the disease by modern methods of diagnosis. Indeed, there is an average period of approximately two and one-half years after chronic pulmonary tuberculosis can be detected before the patient has any sense of ill health whatever. It is during this period that treatment can be administered most successfully. Thus, a positive tuberculin reaction in a patient negative clinically may have a very significant meaning.

X-ray appearances characteristic of past tuberculous infection in a child of 7 with repeated negative tuberculin tests should always be seriously questioned, provided one is sure that the tuberculin used has not lost its potency. In the first place it is an absolute impossibility for any physician to determine etiology from a shadow cast on the x-ray film. Indeed, pathologists often refuse to give any statement concerning etiology of a lesion which they view directly at the postmortem table until they have studied it microscopically. While it is true that allergy may wane and finally become so slight that it cannot be detected by a positive tuberculin reaction, usually a number of years are required for this change to occur. Moreover, it apparently does not occur with great frequency. It is also true that all bacilli in the primary complex may die, soon after which time no tuberculinoprotein is being manufactured in the body to perpetuate the allergy of the tissues, so that it completely disappears. If calcium deposits large enough to cast shadows that can be visualized on an x-ray film have been laid down before this time, they may remain. However, from the evidence available this does not appear to be a frequent occurrence. Although attention has been called to the fact that blood vessels often cast shadows which simulate those produced by deposits of calcium, there is no doubt that many physicians are still interpreting blood vessel shadows as those of calcium deposits. A good example is that of a physician who had x-ray films made of the chests of more than 100 persons who appeared in good health. He took these films to another physician for interpretation. This physician reported evidence of calcium deposits in the hilus region in 97 per cent. He then took them to a second physician, who had no knowledge of any one else having interpreted them. The second physician reported evidence of calcium deposits in the hilus region in 3 per cent. In

a child of 7 years, one's diagnosis of tuberculosis is usually more accurate when based on the presence of a positive tuberculin reaction than when based on the presence of an x-ray film examination in the absence of a positive tuberculin reaction.

CALCULI OF SALIVARY GLANDS

To the Editor:—My wife, aged 40, has been troubled for the past five or six years with what appears to be an excess of calcium salts in the saliva. Most of this has been noted following a radical mastoid operation four years ago, although I do not feel that this has any bearing on the case. The condition was first noted by an excess deposit around the teeth at the roots. Her teeth were hard and white, and there were only about three cavities in the entire mouth, which had been taken care of. However, x-ray examination revealed that practically around all molar teeth and bicuspid teeth this deposit prevented the natural secretions from passing into the mouth and that the bony structure had been so eroded that the roots were just held into the bone by a small margin. There was no evidence of pyorrhea but the circulation of the gums was very poor, the result possibly in part of two attacks of malignant tertian malaria, quinine therapy and a subsequent anemic condition. Almost all these sound teeth had to be removed. On several occasions during the past three years she has had acute obstruction of the submaxillary ducts by stones. All these have been successfully passed without intervention. On one occasion three small stones worked their way to the submaxillary orifice and were removed with forceps. Last week she had all the symptoms of a stone in the left parotid duct. No x-ray examination was available but the parotid gland became swollen while she was eating and the postauricular glands enlarged. It was painful to eat and the mouth was dry. Two days later she told me she felt that the obstruction must have passed, for she felt a flow of liquid in the mouth and then the glandular swelling receded. I feel certain with the history of the case that this diagnosis was correct. Now could you explain this condition to me, if I have made the symptoms clear, and suggest some treatment to prevent the formation of these calculi? The reaction of her saliva is either slightly alkaline or neutral at all times and her oral hygiene is perfect, if such a thing can be. Other than a chronic sinusitis (frontal), her general health is very good. Kindly omit name. M.D., Virginia.

ANSWER.—There seems to be no known method of preventing the formation of calculi about the teeth or in the salivary glands. Their formation does not seem to be an error of metabolism, such as a high calcium content of the saliva, but rather they are of bacterial origin, the bacterial growth producing a change in the secretion, resulting in a calcium deposit about the bacterial matrix.

Frequent x-ray examinations of the submaxillary region by means of a dental film in the mouth should show the early presence of stones, so that they might be removed before they cause any trouble.

CHANGES IN LARYNX OF BOY AT PUBERTY

To the Editor:—What physical changes occur in the larynx of a boy at the age of puberty when his voice changes? Please omit name.

M.D., Pennsylvania.

ANSWER.—According to Quain's Anatomy, up to the age of puberty the larynx is similar in the male and female, the chief characteristics at that period being the small size and comparative slowness of the organ, and the smooth rounded form of the thyroid cartilage in front. In the female these conditions are permanent, excepting that a slight increase in size takes place. In the male, on the contrary, at the time of puberty, remarkable changes rapidly occur, and the larynx becomes more prominent and more perceptible at the upper part of the neck. Its cartilages become larger, thicker and stronger, and the alae of the thyroid cartilage project forward in front so as to form at their union with one another the prominent ridge of the pomum adami. At the same time the median notch on its upper border is considerably deepened. In consequence of these changes in the thyroid cartilage the distance between its angle in front and the arytenoid cartilages behind becomes greater and the vocal cords are necessarily lengthened. Hence the dimensions of the glottis, which at the time of puberty undergo an increase of about one third in the female, are nearly doubled in the male, and the adult male larynx becomes altogether one-third larger than that of the female. (Quain's Anatomy, edited by E. A. Schaefer and G. D. Thane, New York, Longmans, Green & Co., 1898, volume 3, part 4, p. 150.)

Stewart calls attention to the development of the voice in children as being of great interest. At the age of 6 years the boy's voice has a rather narrower range than the girl's in both directions. The boy's voice reaches its full height in the twelfth and its full depth in the thirteenth year, when the range is almost three octaves, its upper limit being a semitone higher than the girl's but its lower limit a whole tone deeper. When the voice "breaks" in boys at the age of puberty, it falls about an octave. The control of the vocal organs becomes so incomplete that only in one fourth of the cases can notes of sufficient

steadiness to be used in music be produced. The vocal cords, as may be seen with the laryngoscope, are frequently, though not always, congested. (Stewart, G. N.: Manual of Physiology, ed. 7, New York, William Wood & Co., 1914, p. 304.)

The larynx at puberty grows considerably, so that the vocal cords in males may increase as much as a centimeter, which is more than one third of the total length. In females the increase in length is considerably less, seldom more than 5 mm. In both sexes because of these changes the voice becomes lower, in the male at least as much as an entire octave. The change in the voice may take place over a considerable period. It may start in exceptional cases as early as at 8 years and, on the other hand, there have been cases observed in which at 18 the singing voice was still that of a child whereas the spoken voice was adult. In the majority, however, both the spoken voice and the singing voice have undergone adult changes. Locally there may be a mild redness of the epiglottis or the posterior portion of the glottis, the vocal cords remaining white. In other cases there is an increased redness and swelling of the mucous membrane of the larynx with the vocal cords also somewhat congested, with the condition in still others in between the two changes described. (Nadoleczny, M., in Denker, Alfred, and Kahler, Otto: Handbuch der Hals-, Nasen- und Ohrenheilkunde, volume 1, Luftwege und Mundhöhle, Berlin, Julius Springer and J. F. Bergmann, p. 638.)

PREVENTION AND TREATMENT OF MALARIA

To the Editor:—What do you consider the best treatment for malaria? I wish to know what you consider an adequate quinine dosage for the average case of malaria. What is your opinion regarding the use of atabrine and plasmochin in the treatment of malaria? Do you think it advisable to give prophylactic treatments for the prevention of malaria in a community where a great deal of malaria exists. If so, what do you advise as a prophylactic treatment for the prevention of malaria? Do you consider it safe to give quinine treatment in full therapeutic doses to a nursing mother? I am thinking of the possible danger of poisoning the nursing baby with quinine. There is a diversity of opinion on this subject and I am anxious to get these points cleared up. Please omit name.

M.D., South Carolina.

ANSWER.—The average case of malaria will be cured if the following quinine dosage is followed: 2 Gm. (30 grains) of quinine sulfate daily given in divided doses of 0.3 Gm. (5 grains) each at intervals of three hours until the acute symptoms have subsided. After this 0.65 Gm. (10 grains) of quinine sulfate a day should be administered for a period of eight weeks.

As the administration of plasmochin is accompanied frequently by toxic symptoms, it should be used with caution in the treatment of malaria. If gametocytes are present it may be given in conjunction with quinine in a dose not to exceed 0.01 Gm. daily for a period of six days. This drug should be used only for the purpose of destroying gametocytes.

Atabrine is undoubtedly an efficient drug for the treatment of malaria but owing to the fact that its toxic properties are still incompletely determined it is not recommended as a routine treatment in preference to quinine. In cases in which quinine cannot be given it should be used but never in doses larger than those usually recommended; i. e., 0.1 Gm. (1½ grains) three times daily for five successive days. In the treatment of hemoglobinuric fever, atabrine should be used in preference to quinine.

The question of the advisability of giving prophylactic treatment for prevention of malaria in a community where a great deal of malaria exists is still *sub judice*. The inefficiency of drugs in prophylaxis and the fact that in such a region they would have to be continued for long periods renders their use inadvisable for the general population. In the case of travelers in such regions, the employees of commercial concerns and troops operating in such regions it has been found that from 0.4 Gm. (6 grains) to 1 Gm. (15 grains) of quinine daily will prevent the development of symptoms of malaria, although this dosage will not prevent infection; for the latter reason the quinine has to be continued for several months after leaving the malarious area to be effective. It would be advisable under certain conditions to use quinine in this way as a prophylactic. The use of atabrine as a prophylactic cannot be recommended; in effective doses it quickly colors the skin yellow and may produce toxic effects in some persons.

An extensive discussion of the relative merits of quinine, atabrine and plasmochin in the treatment of the different types of malaria will be found in the *Quarterly Bulletin of the Health Organization, League of Nations* 2:181 (June) 1933; 4:643 (Dec.) 1935.

So far as possible poisoning of the baby is concerned it is considered safe to give quinine treatment in full therapeutic

dosage to a nursing mother, as there is little evidence that quinine is excreted to any extent in the milk. Practically all the drug taken into the body is excreted through the kidneys or destroyed within the body.

SENSITIVITY TO LIVER PREPARATIONS

To the Editor.—A woman, aged 43, single, has pernicious anemia of several years' standing. She will not take ventriculin because she says that it produces extreme nausea. Capsules of liver extract she regurgitates soon after swallowing. These of course also nauseate and in addition cause gastric distress. Because of failure with these methods I have continued the use of intramuscular injections of concentrated liver extract in solution. Treatment has not been continuously regular because she will not appear for treatment for a considerable period after becoming asymptomatic. About two years ago she had a violent anaphylactic shock with the usual rash, edema of all mucous surfaces as well as some skin surfaces (notably the lips) and difficult breathing, within thirty minutes following the intramuscular injection. This was relieved by epinephrine and codeine. Following this she took no treatment for some months. Then treatment was resumed with no marked reactions occurring. As previously stated, she discontinues treatment against my advice when she becomes asymptomatic. Following one of these periods I resumed treatment and she again had a severe shock as before, after about the third injection. Then after an interval of about three weeks she experienced another shock after another injection.

W. B. FILLINGER, M.D., Ovid, Mich.

ANSWER.—It would seem that the patient lacks emotional stability, as is evidenced by her lack of cooperation in the treatment and her regurgitant proclivities. Anaphylactic shock is an extremely remote possibility following the use of liver extract for pernicious anemia. Although individual variations in sensitivity to medication unquestionably occur, the origin of the anaphylactic reaction in this case must be questioned. Care should of course be taken that the material is not injected into a vein. Older preparations of liver extract contained histamine. Histamine reactions after treatment with liver extract have been reported in the literature. The newer preparations of liver are not known to contain histamine. Assuming that the patient may have an individual sensitivity to this drug, perhaps she could be desensitized by small doses, as is done in anaphylactic reactions with horse serum. Since the patient has pernicious anemia, the treatments that have been tried cannot be improved on. As there is evidence that the hematopoietic principle or principles are stored in the body, infrequent injections of larger amounts than are usually employed may suffice in a case such as this.

HEREDITY IN OPPENHEIM'S DISEASE— MYATONIA CONGENITA

To the Editor.—I have a patient, a mother, with two children, who are described to me as apparently subjects of Oppenheim's disease. These children are unable to stand or walk or use their arms except for a very little, or to hold up their heads well at 3 and 5 years of age. They masticate food and the sphincters are not affected. Their general condition is described as being first class. The mother is now pregnant again and I wish to have your opinion as to a third child being afflicted with the same trouble.

H. H. HARRISON, M.D., Asheville, N. C.

ANSWER.—There is some difference of opinion among neurologists regarding the question of Oppenheim's disease (myatonia congenita) being a hereditary and familial entity. Most of the opinions are that it is neither hereditary nor familial and that one of its most characteristic signs is that the disease tends to improve. Another type of atrophy that one sees occasionally is known as the Werdnig-Hoffman atrophy. This is an infantile condition and is both hereditary and familial and the prognosis is poor. It is possible that the two children have this type of atrophy. If this is the case, the present pregnancy may result in another similarly involved child.

TREATMENT OF ENDOCERVICITIS WITH ENLARGED UTERUS

To the Editor.—A woman, aged 44, normal in all other respects, with a long stringy mucoid discharge of several months' duration, secondary anemia, enlarged uterus about the size of a two months pregnancy, and a large eroded boggy cervix, has regular menstruation, with a larger amount of loss of blood for the first two or three days than normal. Secondary anemia is being satisfactorily treated. What forms of treatment would be advised in such a case?

M.D., Oregon.

ANSWER.—The stringy mucous discharge undoubtedly comes from the glands in the boggy cervix and may be controlled by one or more electric cauterization treatments. However, care must be exercised that the cautery incisions are not made too deep or too near the internal os. The secondary anemia must of course be overcome by various medicinal preparations and the proper diet, but if the excessive monthly flow is a factor in maintaining the secondary anemia it is advisable to stop the flow entirely, especially because the uterus is most likely one

that is generally called a "fibrotic" uterus. Since the patient is 44 years of age there is relatively little harm in producing an artificial menopause by inserting radium into the uterine cavity. In a uterus of this type, 50 mg. of radium should be left in the uterus for thirty hours. If the patient is of a nervous temperament it is better not to destroy the ovarian function by radium. The uterus should be removed vaginally. This operation is safer than an abdominal one. Furthermore, it will enable easy removal of the eroded, boggy cervix, which may lead to further trouble if left in situ even if radium is applied. If the patient is not a good surgical risk, radium should be used to control the bleeding, and the cervix should later be cauterized if necessary.

SENSITIVITY TO PICRIC ACID

To the Editor.—Please give in detail an approved method for desensitizing a person who is hypersensitive to picric acid and to picric acid compounds. The hypersensitivity is manifested by skin reactions which are limited for the most part to those portions of the skin with which the acid comes in contact. The various stages in the order of their appearance and the duration of each stage are as follows: (1) local erythema and intense itching beginning about twelve hours after contact and lasting from one to two days; (2) localized brawny edema with the formation of pin point to pin head size vesicles on the erythematous base, giving a feeling of puffiness, drying and smarting; this stage lasts from two to six days; (3) gradual disappearance of the vesicles followed by scaling of the superficial epithelium lasting from two to four days.

G. E. MARR, M.D., Hamilton, Ohio.

ANSWER.—There is no safe or effective method for immunizing against drugs in general and especially against chemicals producing contact dermatitis. The only practical procedure to be advised is the protection of exposed parts by the use of rubber gloves. If this is not possible a change of occupation is the only measure to be recommended.

TRUMPET PLAYING AND OTITIS MEDIA

To the Editor.—How much danger is there in forcing infection up into the eustachian tube and the middle ear by playing a trumpet while suffering from a mild acute rhinitis with moderate nasal obstruction from swelling of the inferior turbinates? I have a patient, aged 12 years, who has had repeated attacks of otitis media and he plays a trumpet. His last attack of middle ear infection followed a mild acute rhinitis and playing on the trumpet. Is the trumpet playing any factor in the ear infection in this case? Kindly advise whether he should omit the trumpet playing. Please omit name.

M.D., Colorado.

ANSWER.—It is not likely, but it is possible, that in the presence of a nasal obstruction trumpet playing might be responsible for attacks of otitis media. The forcible distention of the cheeks with air while playing this instrument coupled with nasal obstruction would present a situation similar to that known as the Valsalva method of inflating the ears. Should a rhinitis be present, the purulent infected material could be forced into the middle ear cavities. It might be wise in this particular case to cease trumpet playing at those times, at least, when a head cold is present.

HYPOGONADISM

To the Editor.—A boy, aged 14 years, who is well developed and nourished and whose past history is essentially negative except for frequent colds, was operated on for appendicitis five years ago. For the past five months he has been having "hot flashes" frequently and with apparently no relation to anything he does except possibly excitement; he has a headache after any moderate exertion, the cause of which I cannot locate. His body has the aspects of the female body, as also does his carriage and gait. His skin is of a soft texture, his hair is silky, and the distribution of the pubic hair is quite horizontal, as in the female. The penis is of normal size, and the testes are small but well formed. The rest of the body is essentially normal, as are also the laboratory data on the blood and urine. The boy's tendencies are to avoid masculine sports; however, he does like to watch them. Once in a while he plays football but invariably has a headache afterward. Incidentally, the boy has been babied by his mother since he was an infant—she wanted a girl. What is your diagnosis? What is the treatment of choice? Do you think the environmental circumstances predisposed to this condition (being babied)? What is the ultimate prognosis with treatment and without treatment?

M.D., Ohio.

ANSWER.—The fact that the boy has been babied by his mother would have a temporary psychic effect on his future conduct, but such a result will probably not be able to withstand the powerful influences of a normal sexual development. The patient may be given a few injections of the gonadotropic extract of pregnancy urine or placenta (autophysin, antuitrin-S, A. P. L., follutein and the like). Such patients may show marked growth of the external genitals, loss of weight and change to a more masculine bodily configuration after this treatment. Small doses of thyroid may be beneficial.

BILATERAL HYDRARTHROSIS—CHRONIC
SYNOVITIS OF KNEES

To the Editor:—A white man, aged 21, has bilateral hydrarthrosis of both knees. The onset came about two months after an acute gonorrheal infection. The gonorrhea had its onset one year ago. At present there is no discharge from the urethra, and smears are negative. The prostate is normal. The urine contained one pus albumin for about eight months but is now perfectly normal. The knees are painless and the fluid capacity as determined by aspiration is about 2 ounces (60 cc.) in each knee. I should like an expression as to what treatment would be most promising to relief. The Kahn test of the blood is negative and there are no other signs of syphilis. The general physical condition is very good. Please omit name.

M.D., Missouri.

ANSWER.—As the knee condition has existed for ten months, it can be classed as a chronic synovitis, probably gonorrheal in origin. The injection, through a fine hypodermic needle, of 2 cc. of 50 per cent compound solution of iodine into each knee joint, repeated in one week, will be beneficial. In some patients this causes a temporary increase in the synovial effusion, which subsides in two weeks after the second injection. The joint usually then becomes nearly or quite normal.

In case this method of treatment is not finally successful, the knees should be superheated in a baking apparatus for twenty minutes once a week.

The use of hyperpyrexia by the hypodermic injection of foreign proteins, such as typhoid vaccine, repeated once a week, may be of assistance.

EYE IRRITATION FROM OILED ROADS

To the Editor:—Kindly inform me as to the best method of caring for eye irritations resulting from oiling roads.

C. J. PATTHOFF, M.D., Springfield, Ill.

ANSWER.—Crude oil used for oiling dirt roads contains much kerosene and gasoline. Intense heat may drive off the gasoline, and the fumes may be irritating to the conjunctiva. The oiled dust entering the conjunctival sacs, when blown about, causes irritation from the kerosene as well as from the foreign bodies (dust particles). For workers, goggles should be used to protect against the dust.

For conjunctivitis resulting from the irritation, 1:1,000 solution of epinephrine used four times a day along with cold applications for ten to fifteen minutes makes the patient comfortable. A bland ointment such as boric acid ointment used in the conjunctival sac is the only other medication of any value.

ERGOT PREPARATIONS FOR HEADACHE AND
POST-TRAUMATIC HEADACHE

To the Editor:—In "Queries and Minor Notes" in THE JOURNAL January 30, page 416, is a discussion signed "M.D., Texas," entitled "Danger in Ergot Preparations for Headache," in which the description of a typical post-traumatic headache is given. I note that no attempt at treatment is given or suggested except that of the use of drugs. I believe that your answer is rather incomplete, as no mention is made of the use of spinal insufflation of air or section of the middle meningeal artery at the foramen spinosum or of any of its branches. Following the lead of Dr. Penfield of Montreal, many neurosurgeons are using the spinal insufflation of air with considerable success in the treatment of the post-traumatic symptoms. Many times the middle meningeal artery has been ligated at the foramen spinosum or isolated branches at other locations, with relief of certain types of post-traumatic headaches. Personal experiences with both these methods have convinced me that they are of great value in the treatment of the cases after proper study has been made. Naturally, I advise the use of the milder methods first, but after they have been proved of no avail or possibly dangerous the other methods give good results. It is necessary to give the patient careful individual examination and make as nearly accurate diagnosis as possible, before using them. I know of no bad results following either method.

JOHN D. GLECKLER, M.D., San Antonio, Texas.

HEIGHT-WEIGHT-AGE TABLES

To the Editor:—The letter concerning a height-weight-age formula (THE JOURNAL, February 20, p. 666) suggests that two additional kilograms may be of interest. One is the continental rule: Weight in kilograms = height in centimeters — 100. That is, a man 182 cm. tall should weigh 82 Kg.

The other is my own, derived from the Medico-Actuarial Mortality Investigation, and represents a rough approximation of optimal rather than average weights: Assuming that a man 5 feet tall should weigh 140 pounds at age 20, add 4 pounds for each additional inch in height, and subtract a pound for each year beyond age 20. Thus, a man 5 feet 10 inches tall should weigh $140 + 40 = 180$ pounds at age 20, 170 pounds at age 30 and 160 pounds at age 40. At extremes of age and height the results are rather startling, but in general the table will be within 10 pounds of the optimal range, i. e., the weight accompanied by the lowest mortality.

THE FEDERATION OF STATE MEDICAL
BOARDS

FEBRUARY 15—AFTERNOON

Medical Licensure as It Relates to the Practice
of Medicine

DR. EDWARD H. CARY, Dallas, Texas: Those who studied the medical schools at the end of the nineteenth century recognized that little progress could be made in improving the purely commercial schools or in eliminating the low grade institutions without the cooperation of the state licensing boards. As time has elapsed, higher standards have been established in harmony with the ideals of the high type practitioners serving on the licensing boards. The conjoined contribution of the American Medical Association and the Federation of State Boards of Medical Examiners toward higher standards should be appreciated. A generally recognized fact is that graduates of class A medical schools who appear before their state boards experience little difficulty in passing fair technical examinations. With well equipped and acceptable candidates, the question could be raised whether or not the certificate from the National Board of Medical Examiners would be sufficient requirement of examination in medical licensure. If so, many units of licensure that exist in the forty-eight states would be largely disposed of.

Any effort to reeducate the people in the United States to disregard the established idea of regulating medical standards through recognized state boards would in all probability meet the same opposition as would an attempt to abolish freedom of worship or freedom of speech. The members of the boards are usually selected not only for their scientific knowledge which makes them suitable members but for their political acumen as well. Collectively, the board is recognized as a part of administrative government. Doctors should realize the importance of contacts with those who run governments, and such contacts should be conserved and made effective in the public interest. It has been found that medicine can support any measure definitely beneficial to the people and in so doing protects its own interest.

Practitioners in recent years have become acutely conscious of impending legislation affecting their interest. Medicine today in this country would be in a sad plight if it were not organized. Eternal vigilance is required with respect to the many laws and bills touching on medicine and the methods of medical practice. It is impossible to know what political implications may be projected by laymen who are concerned about the methods of practice of medicine. There are those who have manifested a tendency to determine for the profession and the people just what innovations are best. The medical profession has resisted this idea. It believes that in an orderly manner the leaders of medicine, who in a democratic way have had placed on their shoulders such responsibility, will be able to determine the consensus of the profession. These appointed men reflect the general attitude of the profession of medicine toward proposed variations in medical practice. We believe, too, that a solution for the multiple economic and social problems confronting medicine can be ascertained only after consistent and open-minded study of the problems on the part of those leaders deeply interested in conditions as they exist and as they know they should exist in this mechanical or technological age. It is untrue that the medical profession is resisting an orderly transition in its relationship to society. But only through the advantages of their vast experience and knowledge of human needs and a careful analysis of the social

problems can medical leaders point out advisable changes in the interest of both profession and the people.

Various professions are being subjected to pressure based on a desire on the part of the masses to receive the benefits of the learning of its members at a cost which requires little perspicacity on their part. This being true, the dental profession has the same urge to utilize its whole machinery of organization in cooperation with the medical profession to harmonize professional views so that at once we may resist any unwarranted invasion on the rights and privileges which should come to those who prepare themselves for special service and who have in the main utilized their best efforts for public good. Other professions, such as pharmacy and law, are more or less subjected to similar propaganda for change. We must not separate the interests of pharmacy and its board of licensure from medicine and dentistry; their interests are so interwoven that respect and cooperation, one for the other, may be easily commanded. We cannot say as much for the legal profession, yet after all the effort of the American Bar Association to reorganize somewhat along the lines of the American Medical Association will eventuate in better lawyers and high ethical standards. When this is accomplished, the professions mentioned will find themselves more closely allied in their ability to study mutual problems and likely reach helpful conclusions. No professional group wishes to retard the blessings to be derived by the people from advantages of education and experience, but it behooves the leaders of the professions to consider the distribution of these so-called blessings, so that they may be generously bestowed without breaking down the fundamental bases that underlie and support the framework of all education and its happy output.

Years ago the drift of medical graduates away from the country into the cities was recognized. A few thought that lowering standards for the country practitioner would solve the problem. It was not difficult to meet this argument by pointing out that the poorly equipped practitioners, particularly the cultists, succeeded only in cities; in fact, they rarely practiced except in densely populated communities, where their mistakes would be less noticeable. It seems that the trend now is more in the direction of medical men going back to the country than was the case for several years. The board of licensure and the medical profession should definitely cooperate in this problem. The Committee on Legislative Activities of the American Medical Association reported last year to the Board of Trustees that in certain high places the charge had been made that the medical licensure boards apparently were negligent in bringing about the revocation of licenses of the violators of the Harrison Narcotic Act, regardless of whether or not the addicts had been convicted in court of gross misconduct in prescribing narcotics or of gross incompetence in the practice of medicine. It would seem possible for the boards of licensure to find a way to revoke the medical license of this type of practitioner. The profession should take quick and definite action to expel such a man from the county medical society, but we must cooperate to see that the punishment goes further. It is interesting to note that in states like Pennsylvania and New York this narcotic situation is so well in hand that it is not considered of any great moment by the officials of law. The great state of Illinois is not quite so fortunate.

Definitely the interests of the medical profession and the boards of licensure are interrelated. We should be wide awake to the abuse of these special privileges and fight hard to rid the profession of the men who claim the right to practice medicine but violate its obligations. I say this advisedly without recrimination but to urge that all physicians join forces to suppress a great evil. Official Washington feels that it cannot handle successfully the addicts of the profession, whether they have been convicted or not, unless they are supported by wholehearted cooperation on the part of the medical profession and the medical boards of licensure. The board of licensure has found, through long years of experience, that the office of the district attorney and other legal routine has not been effectual in handling illegal practitioners. The development of evidence necessary to substantiate accusations and actually convict the wrongdoer is a highly specialized task. The boards of medical licensure are primarily concerned in protecting the people

against illegal practitioners and quacks. No one can question their unbiased interest in the people. The medical profession is equally unbiased and diligent in conserving the best interest of the people whom it strives to serve unselfishly and well, but who will concede this point?

DISCUSSION

DR. E. SANBORN SMITH, Kirksville, Mo.: I should like to ask of Dr. Cary what arguments were advanced in behalf of the annual registration of physicians? I should like to have Dr. Cary tell us how they have accomplished it in Texas.

DR. C. B. WRIGHT, Minneapolis: We have had the registration law for a number of years in Minnesota. I was instrumental in helping such a law to be passed. We had some opposition from the profession itself and from the profession outside the state. The men we called in consultation from other states felt that it was not fair to the doctors to tell them to pay a reregistration fee to help enforce the law against these malefactors. This was the argument: First, the reregistration of physicians is very important, because in going over the list of men who had passed the board examination we found there were many men who had died some number of years ago, and other men were actually practicing under their names, under their certificates. We also found there were many men who were registered in the state of Minnesota who had moved away and had quit practice. We had no idea as to how many men there were actually in that state practicing medicine. The second thing is the fee. When we went to these men who had passed the basic science law in the legislature and appeared before the committees, we had great difficulty in convincing them, and of course we had a great deal of opposition against the basic science law by the cults and the irregular practitioners. We knew and we were told by the men, by the various committee members and the public health committees, that if we wanted a reregistration we would have to pay for it ourselves, because the legislature would not pass any law or give any appropriation for that purpose. We decided that a reregistration fee which we paid ourselves and which we ourselves controlled through the board would be more valuable. As the money for our board comes not from an appropriation but from a tax that we ourselves pay, that money is pretty well controlled. We feel that we were wise ten years ago in having a reregistration law passed; we were wise in having the reregistration fee, which gives money enough to hire an able investigator, who has done wonderful work in raising the standards and clarifying the situation in Minnesota. Our board wasn't on a high plane before we passed our medical practice act about ten years ago, but we were able to get into that medical practice act this requirement, that the council of the state medical association should nominate three men to the state board of medical examiners. It has been a very important thing in guiding governors to make good appointments.

DR. I. D. METZGER, Pittsburgh: The state of Pennsylvania in 1925 put through a registration act, which was the first act that was passed among the various states. The fee is \$1. No fee would have been attached except for the fact that it is impossible to get any doctor or any one else to register unless they are made to pay. This fee originally was allotted to the state board of medical education and licensure for enforcement of the act. Within three weeks after that time, a law was passed requiring all fees to go into the state treasury and be returned to the various boards by enactment through the legislature. The result was that we had our money thrown into the treasury and we had to get it back. We got it back without much trouble and have had it ever since. Following our registration act in medicine, within a few years a registration act was passed for all the various other boards, some seventeen acting under the department of public instruction. This included the nurses' board, the dental board, the architects' board and others. It has been a very effective measure. The method of procedure now is to have an enforcement officer secured through the attorney general's office, acting under the department of public instruction. His full duty is to enforce the laws of the various boards. He has eighteen or twenty investigators, each delegated to certain portions of the state, and he investigates for all the boards in that particular field. The enforcement officer is in close touch with the various

district attorneys and counties and leads them in the direction of prosecutions. They have been effective because of that fact. It takes away the charge that doctors are trying to defend themselves. We wouldn't think of going back to the old form of having no registration act. It gives the public knowledge of those who are actually entitled to practice. That I think is a very effective means of controlling those who are not licensed. With regard to the art of medicine, last year in my paper I deplored the fact that we had no technic by which we could judge the real genius of a doctor. If a man knew enough, we licensed him to practice. He might not be able to practice at all. We lost something when we quit the apprenticeship system, which was in effect before we had the regular courses in medicine, the preceptor plan. The young man who contemplated the study of medicine would go around to the preceptor and see the various types of work he had to do, the types of cases he had to treat, and, before he got far, he said "I don't want that sort of thing in my life," and he quit. Another man going around and seeing all these various cases of accidents and all that sort of thing would say "That is what I want to do. It is a challenge to me." The medical schools could do something of that type in the aptitude test which is required of medical students now. Why can't we have some technic by which we can sort them out as to whether they are adapted to the study of medicine, not whether they can study or whether they can think or whether they can reason? That is what the aptitude test does now. It fails to touch the very thing we need in the acquisition of medical students.

DR. HAROLD RYPINS, Albany, N. Y.: In New York we have subdivided the functions of those licensing physicians, that is, the state board, and the functions of those who try to get rid of the bad physicians, which is the so-called Medical Grievance Committee. In answer to the question as to how the annual registration assists this particular body, I may say that it assists very largely by providing the necessary funds for having due process of law. We have set aside from the funds derived from the annual registration sufficient money to have two assistant attorney generals who do nothing but act as counsel to the Medical Grievance Committee. We hold a regular court, which is limited to complaints against physicians, in the same way any civil court would hold a trial. The Grievance Committee of New York has now heard over 500 complaints against physicians; about 250 of those are unfounded complaints against physicians; that is, there are just as many complaints against physicians which should not be brought as those which should be brought. The committee has two separate functions. It attempts to discipline those physicians who are acting improperly. We have taken away some forty licenses. We have put about thirty men on probation for one or two years, and we have formally reprimanded and disciplined several dozen physicians. On the other hand, where we have 250 complaints from people, such as "My child had diphtheria and the doctor did the wrong thing and the child died," or "The child was killed from a mastoid operation," there the same committee has had the opportunity to hear these complaints in detail, to allow the physician to make a statement, and to attempt to explain to the complaining individuals that the medical profession has done what was right and proper under the circumstances. We have had annual registration for ten years. I think the profession is satisfied that it is getting its \$2 worth, even though this year the money is being diverted to the state treasury. We have in that law, however, the fact that all fees, fines and penalties derived from the prosecution of these illegal practitioners shall also be allocated to the use of the medical department. In that way the \$2, which in New York State amounts to about \$40,000, is raised to about \$50,000. The medical profession has a right to ask the legislature for these fines, because, as Dr. Wright pointed out, the medical profession is paying out of its own pockets for what should be a tax-paying state function.

DR. ROY B. HARRISON, New Orleans: If memory serves me correctly, California was the first to have registration, and Louisiana was second. We have had it over twenty years. It is written into our law that we have the power to suspend and to revoke licenses. I think if the laws had written into them that the states can suspend and revoke for certain causes, there

wouldn't be any trouble with the violator. We try them and, if we find sufficient evidence, we take the licenses away. The annual registration, as far as Louisiana is concerned, has been very successful.

DR. J. R. NEAL, Springfield, Ill.: Illinois does not have a registration law. In our department of registration and education, as in Pennsylvania, a similar number of boards exist, seventeen professional, trades and occupations. All those but the two professions of dentistry and medicine do pay an annual registration. That money goes into the state treasury and has to be reappropriated to the department. The department has a bureau of investigation. We can't see where the other trades and occupations get any better service from the punitive side of the picture than do the physicians. I have often wondered what is the status of the physician who neglects to reregister and then is sued for malpractice or is sued for practicing medicine without a legal status so to do.

DR. RYPINS: So far as New York is concerned, the law states that the only punishment for failure to reregister is a fine of not more than \$1 for each month of failure.

DR. EDWARD H. CARY, Dallas, Texas: In Texas we realized early that the function of the county attorney, for instance, was to prosecute offenders of the law. The medical profession found that the county attorney, who in many instances had no interest in the matter, frequently had influence brought to bear on him, which caused him not to be interested in the punishment of the individual. In addition to that the county attorney did not stimulate any activity from any source that would bring about information of a special character which would be good in the court. So these things, along with others, justified an appeal to the medical society throughout the state of Texas to submit to a registration law. The board of examiners immediately found it necessary, when it had this much money, to employ the kind of special agents such as detectives, who go over the state and develop the facts that might appertain to some individual and then to put them before the county attorney and bring pressure to bear through the local doctors and others on the county attorney. From that time on I think the board of licensure has been more effective. After long years of experience I realize the importance of whole-hearted cooperation between the practitioners of medicine and the licensing boards. As chairman of the Committee on Legislative Activities of the American Medical Association, I realize how necessary it is for us to have the cooperation of all those forces throughout the United States which can be utilized intelligently at once, to bring to bear some kind of pressure here and there which would aid us in stopping legislation that is not proper. We should be deeply interested in combining the influence of the boards of medical licensure, the boards of dental licensure, the pharmacy boards, the American Medical Association and all, to be well equipped with information and to be thoroughly cooperative, so that we would be able at any moment to use our forces throughout the nation where we want to use them.

DR. THOMAS J. CROWE, Dallas, Texas: Dr. Cary made one slight mistake with reference to the money from the annual registration. It is deposited with the state but in a special registration fund and drawn on only by the state board, on the signature of the secretary and the president of the board, to prevent any one man from handling the money of the board. It is the only thing for the medical profession. I think it is their salvation if the states will adopt some form of registration, one that will provide for official prosecutors.

The Fallacy of Spinal Adjustment

DR. THOMAS J. CROWE, Dallas, Texas: I shall direct attention to a discussion of the nervous system, the spine, and the exhibits with which I hope to prove the fallacy of spinal adjustment. This mounted spine shows nerves and ligaments as they are found on dissection. Observe its five divisions: cervical (neck), thoracic (ribbed), lumbar (loin), sacral (hip) and coccygeal (four lower vertebrae). The sacral and coccygeal divisions, being fused, are practically one bone. The cervical vertebrae are smaller than the thoracic and lumbar. The transverse processes are short and show a foramen on each side for passage of the vertebral arteries, which are life savers when

in slashing the throat both carotids are severed. The spinous processes of all except the seventh, the first prominence felt on running the finger down the back of the neck, are short, turned sharply downward, overlapping from above down, and are deeply buried—from $1\frac{1}{2}$ inches above to three-fourths inch below—by the ligamentous nucha, which extends from the back of the head to the spine of the seventh cervical vertebra, being strongly attached to all the vertebrae between. The nucha is the part on which the wrestler plants a rabbit punch with force sufficient to somersault an opponent, without injury to the spine or vertebrae. The articular processes of the cervical vertebrae, except the two upper ones, axis and atlas, slant from before backward and from the sides inward and downward, so that one cannot be moved appreciably without carrying the one above or the one below it, even when its strong ligaments and the nucha have been removed. On the upper surface of the third cervical vertebra is an upstanding tubercle which fits into a deep depression on the corresponding under surface of the one above it, the axis, fixing the latter so that its long perpendicular odontoid process, which passes through the canal of the first vertebra, the atlas, thus fixing securely the odontoid, which by a strong transverse ligament is held against the anterior arch of the atlas, to which the head is attached, thus forming a pivot on which the atlas rotates when the head is turned from side to side. The ligaments of the cervical vertebrae are so much more resistant than the bony parts that they hold even when the bony parts have been fractured or crushed.

Except that they are larger, their articular processes more sharply slanted and more deeply interlocked by bony processes, preventing movement, the spinous processes much longer and not turned sharply downward, and show the points to which the ribs are firmly attached, what has been said of the cervical vertebrae is true of the thoracic and the lumbar, except that the lumbar vertebrae have no ribs attached. When the thoracic and lumbar divisions are placed in their natural positions movement is impossible, even without support of their binding ligaments. The vertebrae of the sacral and coccygeal divisions, being fused into practically one bone, need not be considered.

All the intervertebral foramina are three times the diameter of the nerves passing through them; a thick cushion of fatty tissue surrounds each nerve, holding it in the center of the foramen, and safely protecting it against pressure even under extraordinary conditions. Except in case of fracture or crushing of a vertebra or laceration of its powerful ligaments, it is impossible to dislocate or subluxate a single vertebra to the point of pinching the nerves passing through its foramen.

Any movement of a thoracic vertebra must carry a rib with it or tear it from its attachment. Further, the articular processes are so deeply interlocked that one of them could not be moved without lifting it and all above it from one-fourth to one-half inch and carrying all superimposed structures with it, in order to release it from the interlocking socket of the one below. The nineteen powerful ligaments of the spine are powerful enough to resist a force sufficient to fracture, even crush, the dense bony parts of the vertebrae and reduce the softer body part to a powder, as proved by actual test.

The surprising thing about the subluxated or slipped vertebra is that, according to adjusters, it will not stay put; that, unlike other dislocated bones, and notwithstanding its interlocking articulations, intervertebral fibrocartilage, supporting ribs and numerous sustaining ligaments, it has to be readjusted every day or two, regardless of what ails the unfortunate patient—whether whooping cough or stone in the kidney. It sounds like the story of the Indian doctors who cure people by throwing them into a fit. Having shown the contacts of the cerebrospinal nerves with those of the autonomic system; that the ganglionated autonomic system gives nonmyelinated gray filaments to all the spinal nerves but receives in return myelinated white filaments from only thirteen anterior roots of the cord, and these are grouped in only four ganglia of the sympathetic division of the autonomic; that more than half of the autonomic system has no connection whatever with the spinal cord; that the ganglia of the autonomic, even the intrinsic ganglion of an organ, will maintain its function after it has been freed of other innervation; that the sturdy interlocking articular processes of the vertebrae, intervertebral fibrocartilage, supporting ribs,

nucha and numerous powerful ligaments—actual specimens and charts of which are presented—all serve to make the manual movement of a vertebra in a living person impossible, except when the bone is fractured or crushed by a powerful blow or a crushing force (when the ligaments usually hold so that traction produces realignment of the fragments), I submit this paper for consideration and decision as to whether the claims made for the beneficence of spinal adjustment should be regarded as fact or fallacy.

DISCUSSION

DR. THOMAS J. CROWE, Dallas, Texas: The paper was not intended as a criticism of method at all, but I hear in the courthouse all the time about the spinal adjustment business. We shall never get anywhere until the public realizes what scientific medicine means.

The Doctor and the Narcotic Violator

DR. R. L. SENSENICH, South Bend, Ind.: The Bureau of Narcotics reported the detection of 5,200 criminal violations of the Harrison Narcotic law in 1935 and conviction in 2,065 cases in the same year. There is nothing in the Harrison Narcotic Act or in the laws of the various states prohibiting treatment, reasonably planned and carried out, in an effort to effect a cure of narcotic addiction. It should, however, be emphasized that any type of ambulant treatment of average addicts, outside of institutions, uncontrolled and dependent on the voluntary reduction of the narcotic, is recognized to be ineffective. From this basis such treatment must be admitted in itself to be a violation of narcotic laws by the administering physician. Even treatment in institutions not organized for treatment of narcotic addiction and without specially trained personnel for the care of addicts is discouragingly unsuccessful. Narcotic addiction has a psychologic basis, and the performance of any cure is dependent on the intelligence of the patient, adequacy of the psychologic adjustment, and completeness of the personnel and environmental rehabilitation attained. Obviously, little can be accomplished without institutional and sociological facilities such as are not now available to the average physician. It would seem proper for the medical profession to encourage broadening of the activities of ethical institutions under competent medical management to include such supervision and assistance after discharge as would make possible some salvage from this group of addicts. Some might necessarily be treated at public expense, but no progress can be made in the reduction of existing addiction without institutional treatment. For the confirmed addict little can be done when personality defects make rehabilitation impossible. A study of 946 addicts in 1935 revealed an extremely high criminal record, as reported by the Bureau of Narcotics of the Treasury Department.

What manner of individual is the medical narcotic violator? A study was made of available histories of physicians convicted of narcotic violations. The following is a description of the narcotic violators studied: The average age determined was 60; the youngest was 41 and the oldest 67. Thirty per cent were of foreign birth; 20 per cent were natives of this country; in 50 per cent, places of birth were not recorded. The pre-medical education of 10 per cent was reported in foreign institutions, 30 per cent in American universities, and in 60 per cent there was no record. The medical education of the group was as follows: Two were not graduates in medicine. Fifty per cent of the medical schools from which graduation was reported are extinct and were not of acceptable standing according to the standards of medical education at the time the men were graduated. Only one physician in the group indicated interest in any specialty, that being public health work. Thirty per cent of the number were convicted of other criminal offenses in addition to violation of the Harrison Narcotic Act, falsification of government reports, and forgery of prescriptions, incidental to the narcotic violations. Fifty per cent of the number repeated the violation of narcotic laws after release, some having served two or three terms of imprisonment. Twenty per cent of the number, in the course of their trials for violation of narcotic laws, admitted narcotic addiction.

When the state agency whose duty it is to enforce the narcotic laws disregards conviction in federal court for acts which are also violations of neglected state laws, in themselves sufficient basis for disciplinary action, it tends to break down respect for

the law and the manner of its enforcement. Judgment of physicians is sometimes swayed by the implied doubt as to the fairness of the conviction, the character of the evidence or the importance of the law. Irked by the annoyance of required records, and narcotic license and tax, it is easy to lend sympathetic ear to the individual who complained that he was convicted on a technicality. Color is given to this statement when the state licensing body which has the records of the case, or may readily obtain them, chooses to disregard the conviction. Federal authorities have repeatedly stated to the Committee on Legislative Activities that no action is brought against a physician until it is established that he is a conscious violator of the law in a major respect, and then only after he has been warned to cease the violation and given opportunity to comply. The names of those known to be addicts, and names of those convicted of narcotic violations are furnished to the proper state licensing agencies by federal authorities, and not to the private physician or his local medical society. The by-laws of constituent and component societies of the American Medical Association should contain specific provisions that conviction of federal or state narcotic violation shall constitute a cause for expulsion from the medical society. Even with this provision, action may be neglected because no member wishes to take the initiative in invoking the expulsion clause. Action should then be instituted by the state association or by the Judicial Council of the American Medical Association, as continuation of individuals, convicted of crime, in membership of medical societies reflects unfavorably on the whole group. The physician may disapprove of a suspected delinquent on the basis of information personally acquired. The status of the violator is directly governed by the action of the state licensing body in whom authority to judge and take disciplinary action is invested.

Some state licensing boards apparently operate effectively, but there is reason to believe that other states operate ineffectively. Inadequate or cumbersome legal structures should be corrected. The uniform narcotic law, with minor modifications to meet special needs or fit into the legal structure of the various states, offers some advantages. The medical profession might well assist in promoting advisable changes in law. In the routine administration of laws, making certain actions mandatory and others optional only within certain limits, the broader purpose of the administrative unit apparently is sometimes forgotten. There should be the closest cooperation between the private physician and the state licensing board in dealing with the narcotic violator. Recognizing the importance of maintaining high medical standards, and the responsibility of organized medicine to the public, the doctor will support the just administration of laws relating to the narcotic violator.

A Lawyer's Point of View on the Narcotic Problem

MR. HERMAN B. CARLSON, Des Moines, Iowa: To enforce the narcotic statutes without consideration of humane impulses and the conservation of the victim, whether vender or addict, is not altogether a simple problem, nor is it easy to conclude that is the thing to do. The attention of the world has been gripped by the pronouncement of a war lord in China that all drug addicts who have not given up the habit by Jan. 1, 1937, are to be executed. Indeed, according to newspaper reports more than a hundred were at a single execution rite shot and killed in the Chinese manner. It seems that hundreds of thousands more are doomed to that same punishment. We in America believe that the drug addict is more unfortunate than vicious, and while strict enforcement of penalties is justified, we acknowledge not our wisdom but our poverty in understanding, because we know of no better remedy.

State officials are sometimes criticised because reported violations are not followed through to prosecution, revocation of license to practice and confinement of the vender. On the theory that fire can best be fought by fire, law enforcers and investigators who measure their achievements in statistics and not in the betterment of men have adopted the stool pigeon method of ferreting out the offender. Too frequently a victim must be found by the stool pigeon or he doesn't keep his job. As a rule the least culpable are the least suspicious and the most easily "entrapped." The penalties of internal revenue violations and threatened prosecution scare the doctor and he just doesn't know what to do. His honor, his reputation and,

most of all, his family's reputation is best preserved by having the least said. He compromises and pays his penalty. Shall he have his license to practice revoked? Possibly human intelligence in the inflicting of penalties should not be used. This is not the view of the Federal Bureau of Narcotics, for Mr. H. J. Anslinger, commissioner, in the proceedings of this congress in 1934, page 53, said: "A compromise is usually an admission that one cannot go through with the prosecution. Cases are compromised for a number of reasons: Sometimes witnesses are in another jurisdiction or have died or have left the service. We never compromise a case unless the United States attorney definitely makes a statement that he approves of a compromise and does not believe the case should be prosecuted." It seems to me therefore that when a delinquent physician has been reported and he has compromised we must consider him as one of whom suspicion is justified and he should be fairly well watched. He deserves admonition but hardly prosecution. It has been my effort not to plunge into a prosecution or revocation. I have felt I should make independent inquiry; doctors are usually poor lawyers. I have discovered doctors who, without the advice of counsel or appreciation of the inherent consequences, have pleaded guilty as an easy way out. I may have erred but I have used my best judgment in arriving at a conclusion as to whether I should insist on revocation.

Licenses have been revoked and suspended and will continue to be revoked and suspended. In some cases it is the prosecutor's duty to be vigorous and relentless and in some instances to temper justice with mercy.

I have felt that a wholesale revocation of medical licenses would serve no good purpose in developing confidence of the public in the physicians. I have felt that the profession cannot retain its standing and merit unless out of it are driven those few parasitic members who use a fine calling as a screen to iniquitous traffic. For them I have no plea for leniency. I have felt that most doctors are entitled to a helping hand of a prosecutor if there is manhood left worthy to salvage; if the danger is not too big.

Every member of the profession owes it to himself, to his professional brother, to the profession and to the community to save and not destroy the senses of the citizen. He must not, he dare not and he cannot traffic in drugs for addicts and survive.

DISCUSSION ON NARCOTICS

DR. WILLIAM C. WOODWARD, Chicago: There has been criticism leveled at the profession because of the failure of its examining boards to act properly on evidence submitted to them that certain members of the profession are drug addicts and therefore presumably not capable of practicing their profession with safety to the public. The complaint is not that they do not revoke the licenses of drug addicts but rather that they don't even hear the evidence in the cases when it is offered to them. There are various degrees of culpability in violations of that character, but that doesn't excuse the board from saying to the Commissioner of Narcotics, when he submits the evidence to them that a man has been convicted of violating the local law or the federal law, "Let us have your evidence. We will hear the case, and after we have heard the evidence we will determine what to do and assume the responsibility for it." Again, the criticism is not of their unwillingness to revoke the license but primarily of the unwillingness of the board to hear the evidence and to assume the responsibility for allowing a person convicted of violating the law to continue as a practitioner, when it is practically certain he will continue to violate the law at every opportunity. Something has been said here with respect to the conviction of these men through the use of stool pigeons. I hardly think my legal brother is going to assume that many of the physicians who have been convicted of violating the Harrison Narcotic Act have been convicted through the use of stool pigeons.

DR. WALTER L. BIERRING, Des Moines, Iowa: Every single one in Iowa.

DR. WOODWARD: A stool pigeon is used because the law enforcement officers have substantial reason to believe that the man is violating the law; if it can be shown in court that there is no substantial reason, the evidence will be thrown out.

Those convictions in Iowa rather reflect on the legal profession there as well as on the medical profession, because the evidence of stool pigeons would have been thrown out, if the statement that has just been made by the president of the State Board of Health of Iowa is correct. I do not believe that the Federation of State Medical Boards or the individual members of the federation can afford to go on record as being unwilling to hear the evidence and as unwilling, after having heard the evidence, to assume the full responsibility for saying to the public "Dr. So-and-So is an addict but we are going to let him practice. Dr. So-and-So has been convicted of violating the state or federal narcotic law but we think that won't do much harm. We will assume responsibility for that, and we are going to let him go."

DR. WALTER L. TREADWAY, Washington, D. C.: It is significant that this federation has on three occasions in the past several years undertaken to discuss the subject of the seriousness of narcotic drugs and their relationship to the medical profession. I believe that this problem can perhaps best be met through an educational program, through an understanding, through conferences of this sort, and through an appreciation on the part of the licensing agencies of the several jurisdictions as to the seriousness of this problem. Several years ago, I think in 1931, there was a series of articles in *THE JOURNAL*, prepared by a group of men representing the various specialties of medicine, on the indispensable uses of narcotic drugs. They were put out in book form and, like all first editions, contained many errors, perhaps. We have been restudying that situation with the idea of formulating for the general profession an informative memorandum that could be handed to a man who was suspected or who had been buying in excess of the quantities of narcotic drugs that would be needed in ordinary practice. In some instances a man who has one foot on the ethical side and the other just on the outside of the profession will buy large quantities of drugs, either to take for himself or to dispense or prostitute his profession for the satisfaction of addiction. When an enforcement man comes to visit him, he says "I have a cancer patient, and I have been administering these drugs in this inoperable case." It is remarkable how one can manage a cancerous patient on a small amount of opium. Men at the Pondville State Hospital in Massachusetts, assisted by one of our officers, demonstrated that many cases could be handled with codeine and with acetylsalicylic acid. Sometimes the claims of these practicing physicians that they need large quantities of opium for the management of cancerous cases are not in keeping with the indispensable uses of these drugs. The profession has developed a custom in the use of drugs. For example, when the quantity of drugs necessary for medicinal and scientific purposes in the United States is analyzed each year to fix the quantity of raw materials to be imported, it is found that the retailers and the physicians in different parts of the country use a different quantity of drugs. For example, to take a state which has a homogeneous profession, a great many of the practicing physicians in Indiana are graduates of the University of Indiana. One finds within that state a low per capita consumption, in a legitimate channel, in the use of morphine, and a relatively high per capita consumption of codeine. Some of the other states present an altogether different picture, a large per capita consumption of morphine. I think that some of that morphine is being used ill advisedly and, in some instances, it is being used directly in contravention of the law. I should like to mention the cooperation that we have been receiving since the government opened the first narcotic farm at Lexington, Ky. That institution has 1,000 beds. Those eligible for admission are those convicted of offenses against the United States, those who have been placed on probation by courts of jurisdiction, one condition of probation being that they go to this farm for treatment, to remain until cured; and, third, the voluntary case. We have no facilities for women. In several states adjoining Kentucky the licensing boards that have had physicians who were a little irregular have said "Now here the government has facilities. You go to this institution as a voluntary case and get yourself on your feet, and when you return we will allow you to practice over here, but if you kick over the traces another time we will revoke your license." The success that we have had with those people

who have been coerced and have had something to lose has been extraordinary. Sometimes a man gets into a mental attitude of life and continues the use of these drugs, and then suddenly some one gives him a chance or an opportunity for getting on his feet and he is able to come back. If an addict is brought before a federal court and the sentence is stayed, the court may place such a person on probation for a period of five years. That means he goes to the institution for a year, six months, or what not, and when he leaves he returns again to the jurisdiction of the probation officer, the federal government exercising supervision over him for the remainder of the five years. That is the only social set-up which the government has. We are going to have a second institution at Fort Worth, Texas, that will have 1,200 beds. That is an attempt on the part of the federal government toward a partial solution of this so-called addiction problem. We have been agreeably surprised with the results obtained in the operation of the first institution at Lexington, and we hope that the probation clause of the law will be used to rehabilitate, if possible, the men of the profession who might be somewhat irregular but might be given an opportunity or a chance to come back.

DR. I. D. METZGER, Pittsburgh: We have a method of procedure in Pennsylvania that helps us in the administration of narcotic cases. We have a division of narcotics under the bureau of health which acts administratively in respect to these cases. A number of doctors are under suspicion. They are warned. They are told about the danger of revocation. Many of them steer clear of coming to the focal point in respect to the matter. That helps us mightily. When the case is presented to the board, there is evidence presented which proves the fact. The evidence is gained in this way: Under the Pennsylvania law, all narcotic drugs must be reported to this division in Harrisburg, by pharmacists, at the end of the month. Of course, narcotics cover several other dangerous drugs. That narcotic division sorts out these prescriptions, finds out that a certain person has purchased a lot of narcotics and prescribed them, and, through its investigators, it finds out the method by which they have been disposed. I am afraid that a lot of our young doctors are led to prescribing narcotics in an inordinate manner, because they are taught to do that in hospitals. I want to give that warning here. We have found in Pennsylvania certain hospitals out of which have come young doctors who served as interns who are all using much more of this type of drug than they should. We found other hospitals in which doctors who have been trained in those hospitals rarely use narcotics. We ought to get back into the hospitals and sound a warning to members of the staffs of the hospitals, and we are doing it in our state, to see if we cannot shut off this initiation in the course of training of the young doctor of the inordinate use of narcotics.

DR. J. F. DU BOIS, Sauk Center, Minn.: This subject is pertinent to Minnesota. It seems to me that, if our examining boards can be in close touch with the federal department, many prosecutions by the federal department could be prevented. We can chastise our doctors or put them on probation, and if they don't listen to that they can be taken care of more harshly.

DR. R. L. SENSENICH, South Bend, Ind.: I tried to develop in my paper the fact that there may be difficulties about the administration of the law. The thing I have tried to stress is this: Let us deal with the narcotic problem in such a way that we shall leave no doubt as to how it is being handled. We can count on the medical profession standing back of us and cooperating in the administration of these laws on a safe and sound basis.

DR. ERWIN SCHENK, Des Moines, Iowa: So long as the federal courts convict, why do they not withhold the permit to use narcotic drugs until that person is reinstated? Why does it come up to the boards to revoke?

DR. WOODWARD: The Federal Narcotic Bureau has no authority to revoke the permit and can have none, under the federal constitution. A man's right to practice medicine, including the use of narcotic drugs, depends on a grant from the state. The most the federal government can do is to regulate the exercise of that right, not forbid it.

MR. HERMAN B. CARLSON, Des Moines, Iowa: The constitutionality of the Harrison Narcotic Law is based on the

fact that it is a revenue measure, and the physicians who have been arrested or who have compromised cases have found that it is a revenue measure.

Some Problems in Medical Licensure of Massachusetts

DR. EDWARD A. KNOWLTON, Holyoke, Mass.: The medical practice act in Massachusetts is one of the first in the United States to be drawn, and it has never been materially changed since it was enacted in 1893. The seven physicians on the board are appointed by the governor for a term of seven years. There is no permanent executive or administrative officer, such as many boards have. The act provides that not more than three board members—a minority—may be members of the same incorporated medical society, and that no member may be from the faculty of a medical school. When the act was drawn there was apparently more than one really strong or solid system of medicine. As time passed, the various types or cults of the practice of medicine have faded from the field and now only one real form of medical practice is taught—the regular school. With the passing out of these cults their respective medical societies have dwindled in strength to almost nothing, yet our laws have not been altered. As a result, our board never has a majority who are members of the American Medical Association or of the state society. To prevent the creation of a second examining board at the urgent demand of a very small but well organized minority, the governor appointed an osteopath to the board, and each succeeding governor has appointed an osteopath when the seven year term of that appointee has expired. The state society, with a membership of about 5,000, is not by law permitted to have more than a minority representation on the state board. The small minority of 6,000 practitioners of the state always has a majority representation. The personnel of the board is therefore not a true or fair representative body of the majority of our practitioners, and a large number who might be very constructive and able board members are not eligible. The restriction as to board personnel is therefore one of the problems of medical licensure in Massachusetts.

Our medical practice act compels us to take for examination any person who is graduated from a high school or its equivalent and who has received a degree of M.D. or its equivalent from any incorporated and legally chartered school. Practically we have to admit for examination anybody who has a degree in medicine irrespective of the school from which the applicant comes. And they seem to come to Massachusetts in hordes from all over the world. During 1931-1935 we accepted for examination graduates from sixty-nine schools that are approved as class A or in good standing by the American Medical Association. During the same period we accepted graduates from twenty-nine schools that are not recognized by the American Medical Association or are classed as "not approved," a total of ninety-eight schools. All told, there were 2,003 applicants for examination. Of these, 712 (35 per cent) came from the approved schools and 1,291 (65 per cent) from the nonapproved schools. We passed and registered by examination 518 graduates from the approved schools, 83 per cent of these applicants, or 29 per cent of all applicants. In the same period we failed to pass or refused to register by examination 1,073 graduates from the nonapproved schools, 83 per cent of those from the nonapproved schools, or 53 per cent of the total number of all applicants. The total number of failures of all the 2,003 applicants was 1,188 (59 per cent). The graduates of the approved schools accounted for about 9 per cent and those from the nonapproved schools for about 91 per cent of these 1,188 failures.

Our law provides that the applicant shall be examined in seventeen subjects. We divide these seventeen subjects into seven groups of ten questions each. Each board member examines one group. The result is that the examinations are hodge podge and a smattering of this and that subject with equal evaluation of each. An applicant may fail to pass any of the clinical subjects and yet receive high enough marks in the premedical and nonclinical subjects to give him a high enough percentage mark to be certified. Another applicant may receive relatively high marks in the clinical subjects and because of low ratings in his premedical and nonclinical sub-

jects fail to attain a sufficiently high percentage rating to be licensed. There is no provision in our act for oral examination or an inquiry into the applicant's personal qualifications to practice medicine. We license or refuse to license applicants entirely on the results of these smattering written tests of the applicant's academic knowledge.

I will mention a few other problems of licensure in my state which I will not discuss: The reexamination of applicants who have repeatedly failed; it is not uncommon to reexamine an applicant from ten to fifteen times and a few have taken the examinations more than twenty times—we have no privilege to refuse their applications for reexamination. The examination of physicians registered in other states who wish to practice during the summer months in the various resorts of Massachusetts; most of these applicants are practitioners of ability and good repute, yet our law does not permit us to give them any special or oral examination. The reinstatement of physicians whose registrations have been suspended or revoked because of gross professional misconduct. Lastly, the ever increasing amount of insidious pressure that is put on the individual board members by some persons in the state government or by some persons close to it to favor this or that applicant for registration irrespective of the applicant's personal or academic qualifications. Often the least qualified applicants seem to have the most influential backing. It is rather rare to have anybody speak a good word for a graduate of an approved school.

Our problems in medical licensure in Massachusetts, therefore, are due almost solely to an out-of-date and clumsy medical practice act. It could be probably entirely rewritten if the state medical society would show real interest in changing it. There seems, however, no such interest. Instead, there seems to be an apathy bordering on an aversion of the society to do anything that will raise or improve the standard of practice in Massachusetts by changing the medical practice act. The backing of the society is absolutely essential before any real good can be accomplished. The board has from time to time submitted bills to the general court to improve the act, but it has met with very little success at the legislative committee hearings. At these hearings the rooms have usually been crowded with an organized and active group of nonmembers of the state society—usually graduates of the so-called nonapproved schools who are opposed to the making of any change. Usually a member or two from the state society has been present to register his approval of the board's proposal, but their efforts have been feeble as compared with the large organized groups of nonsociety members. As a result, practically no material improvement in the act has ever been accomplished. It is my opinion that none ever will be made until the state society shows an interest.

DISCUSSION

DR. I. D. METZGER, Pittsburgh: I should like to get a vote on the reexaminations. How many boards here give only one examination? (Three.) How many give two on the same fee? (Five.) How many give three on the same fee? (Three.) How many give an indefinite number on the same fee? (One.) I think the limitations in the law have been changed. They used to have it open to all, as you have, but that is being changed in all the states now. Our board will give two examinations. They may not take the third examination until they have had a year of work which has been outlined by the board. In our board they either fail or do not fail. They take the whole examination again. They must qualify by having had a year's work, approved by the board, before they may enter into another examination. They get two throws if they want to, on the second trial.

DR. STEPHEN RUSHMORE, Boston: Through my familiarity with the unrecognized medical schools in Massachusetts (and I have been in varying contact with some of them) we have learned how to evade the law. The students in one of the schools told me that, in their course on legal medicine, they were told never to break the law; it is unnecessary; you can always get around it. So the way we have evaded the law in Massachusetts concerning membership in the state medical society is to have a man who is not a member of the society, who he or his friends think may become eligible. So we have

on the board six men; three of them are nonmembers of the state medical society and three members who have resigned from the state medical society during their membership on the board. So from the point of view of informal representation the society has six members on the board; formally, of course, only three. I was one of those who resigned from the medical society to go on the board. Of course, it is a matter of astonishment to a great many people to find that the secretary of the board is not a member of the medical society. The board asked that it might have the power of approval of medical schools. The legislature, in its wisdom, saw fit to create a new organization consisting of the commissioner of public health, the commissioner of education, and the secretary of the board of registration in medicine. These three have the power of approval of colleges, so far as they give premedical education, and of medical schools. The act does not become effective for two years, Jan. 1, 1939, so that we are at present on the old basis and have to admit to examination practically anybody who comes along. We did manage to reject one man from a medical school in Chicago, a school that was run in connection with chiropractic. He had not had four years in the school, although he had gotten his degree. He has to be in the school four years. The late development is that, since this law has gone into effect concerning the approving authority, and that means schools of osteopathy will have to meet, so far as our board is concerned, exactly the same standards as other medical schools, the osteopaths have introduced a bill to have a separate board of registration for osteopathy. Also, the chiropodists have introduced a bill. They want to break away from the board of registration in medicine. Of course, we have the chiropractors every year. The board has again this year introduced a bill providing for annual registration of physicians. They introduced a bill last year and the Massachusetts state society opposed it. I think there is a fair chance that the society will oppose it again this year. Then the question will come up as to whether it is wise to drive it through over their opposition or whether it is better to wait another year and try to educate the society. As you can understand from our remarks, the society needs educating.

DR. H. J. LEHNHOFF, Lincoln, Neb.: I should like to ask the representative what the attitude of the medical schools is with regard to the condition.

DR. EDWARD A. KNOWLTON, Holyoke, Mass.: Three medical schools of the state are approved by the Council on Medical Education and Hospitals, and there are three schools which are not approved. The three schools which were disapproved are content, and the three schools that were approved are content. So it is kind of a no man's land, that all the approved schools' men are accepted for examination and the nonapproved schools' men are accepted for examination. They are all content so far as that part of the law goes.

DR. J. EARL MCINTYRE, Lansing, Mich.: I should like to ask Dr. Knowlton why the Massachusetts law makes it necessary for those from other states to pass the examination but it accepts National Board rating.

DR. KNOWLTON: That was done before I was on the board, I don't know what board, but we accept those who pass the National Board, on their ratings.

DR. MCINTYRE: Is there any other reason why the other states should be discriminated against?

DR. KNOWLTON: The law has never been changed. Usually if men want to come into the state from outside they have to take the regular examination which the recent graduates have to take.

DR. ROY B. HARRISON, New Orleans: Did I understand that it is written in your law that you will accept members who passed the National Board but that you will not accept applicants from out of the state?

DR. KNOWLTON: If the man passes the National Board, we register him in our state, but we are not allowed to accept applicants for registration who are registered in other states, on other boards' qualifications. We can't accept the say-so of any board as to the qualifications of a man. We have to examine him in writing. The law specifically says so.

(To be continued)

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL, April 3, page 1207.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I and II*, May 10-12, June 21-23, and Sept. 13-15. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

SPECIAL BOARDS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Written examination for Group B applicants* will be held in various cities throughout the country on April 17. *Oral examinations for Group A and B applicants* will be held in Philadelphia, June 7-8. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: *Practical examination* will be given in St. Louis, April 23, and at Philadelphia in June. Chairman, Dr. Walter L. Biering, 406 Sixth Ave., Rm. 1210, Des Moines.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Practical, oral and clinical examinations for Group A and B applicants* will be held at Atlantic City, N. J., June 7-8. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY: Philadelphia, June 7 and Chicago, Oct. 9. *All applications and case reports, in duplicate, must be filed at least sixty days before the date of examination.* Sec., Dr. John Green, 3720 Washington Blvd., St. Louis, Mo.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Atlantic City, N. J., June 8. Sec., Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: Philadelphia, June 7-8. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PEDIATRICS: Atlantic City, N. J., June 6. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Illinois.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: Philadelphia, June 2. Sec., Dr. Walter Freeman, 1028 Connecticut Ave., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: Atlantic City, N. J., June 4-6. Sec., Dr. Byrl R. Kirklín, Mayo Clinic, Rochester, Minn.

AMERICAN BOARD OF UROLOGY: *Oral examination.* Minneapolis, June 25-26. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.

Pennsylvania Reciprocity and Endorsement Report

Dr. James A. Newpher, secretary, State Board of Medical Education and Licensure, reports 15 physicians licensed by reciprocity and 5 physicians licensed by endorsement from Sept. 15 through Dec. 18, 1936. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Howard University College of Medicine.....	(1934)		Maryland
State University of Iowa College of Medicine.....	(1931)		Iowa

Book Notices

Textbook of General Surgery. By Warren H. Cole, M.D., F.A.C.S., Professor of Surgery, University of Illinois College of Medicine, and Robert Elman, M.D., Associate Professor of Surgery, Washington University School of Medicine, Saint Louis. Cloth. Price, \$10. Pp. 1,031, with 559 illustrations. New York & London: D. Appleton-Century Company, Incorporated, 1936.

Cole and Elman deserve considerable credit for this new book. They have undertaken the enormous task of compiling in book form the fundamentals of general surgery as presented to their students, especially those in the junior year. In their introduction they state that the material used is based on lectures to undergraduates and intended primarily as a textbook for their use. Their ability to condense such a subject is based on years of teaching experience, not only in the laboratory but also in clinical medicine. The sequence of the material is well arranged not only for the beginner but also for the advanced student and general practitioner. The fundamentals of inflammation and repair, surgical bacteriology and immunology, asepsis and antisepsis, and the spread and localizations of infections are first presented. A chapter is devoted to each, emphasizing that fundamental knowledge of anatomy, physiology and bacteriology is prerequisite for an undertaking of surgical diseases. Surgical conditions of the various systems are then taken up in order. The descriptions are classic, and typical illustrations of the disease condition are given. The illustrations are rather diagrammatic and do not come up to the standard of the rest of the book. All portray the point in question; a few are excellent, but many could have been replaced by reproductions of actual photographs. The authors cover the subject fully in its broader concepts and do not attempt to discuss the minute details and atypical conditions. The tremendous task of condensing into one book the fundamentals of general surgery is excellently done. The work is modern and authentic, and it presents the present-day views in a concise and clear manner. Of great value is the complete bibliography of authoritative literature which follows each chapter and which serves as a further reference for those interested. In the two chapters on gynecology and genitourinary surgery an attempt is made to cover in a few pages these surgical specialties. They are less valuable than the other chapters of the book. At the conclusion is given a short discussion on obtaining a history and physical examination of the patient, in which the importance of a good history is stressed and the principles of an adequate physical examination are outlined, both of which are too frequently overlooked. The work is of merit and its value to the student and practitioner cannot be questioned.

La hipofisis: Sus funciones en la clínica. Por el Dr. Mario Scheitengart, docent libre de patología médica de la Facultad de medicina de Buenos Aires. Paper. Pp. 223, with 42 illustrations. Buenos Aires: Aniceto Lopez, 1936.

In this volume the author has endeavored to describe in more or less condensed form the normal functions of the pituitary gland and certain clinical syndromes caused by the malfunction of one or more of its components. The main emphasis is placed on the more generally known principles, such as the growth, gonadotropic, thyrotropic and metabolic fractions. They are dealt with splendidly from a physiologic point of view and to a certain extent also from the histologic, developmental and pathologic side. One misses, however, an adequate description of the almost equally well known para-

thyrotropic, diabetogenic, adrenotropic and lactogenic hormones, as well as those derived from the pars intermedia and the posterior lobe. This is unfortunate, since the title of the book would lead one to assume that all the parts of the hypophysis are considered with equal thoroughness. In describing the clinical disease entities the author has taken his material from the literature and added to it case reports from his personal experience. There are a number of fine illustrations of patients representing various pituitary endocrinopathies, and reproductions of roentgenograms and histologic slides. Some of these illustrations are borrowed from standard textbooks, partly American and partly foreign, while many are originals. It seems that the clinical sections are not nearly so adequately treated as the theoretical portions of the book, even though the title would suggest this to be primarily a clinical treatise. This is probably due to the evident leaning of the author toward the fundamental sciences. The sections devoted to the specific dynamic action of foods and to the metabolism of fats, proteins and carbohydrates, together with that dealing with the part played by the pituitary on salt and water balance, are among the best in the book. Here too the laboratory has fared better than the clinic. At the end of every chapter there is a list of bibliographic references. Considering the size of the book, they are well chosen and cover a good many in languages which the average American student can read. While no fully encompassing view of the clinical features of pituitary diseases is presented, Dr. Scheitengart covers well the principal facts of our present knowledge of this complicated gland. It should therefore furnish a valuable addition to the library of the practicing physician.

Recent Advances in Allergy (Asthma, Hay-Fever, Eczema, Migraine, Etc.). By George W. Bray, M.B., Ch.M., M.R.C.P., Physician in Charge of Children's Department, Prince of Wales Hospital, London. With foreword by Arthur F. Hurst, M.A., M.D., F.R.C.P., Senior Physician, Guy's Hospital. Third edition. Cloth. Price, \$5. Pp. 517, with 101 illustrations. Philadelphia: P. Blakiston's Son & Co., Inc., 1937.

The appearance of three editions during the last five years indicates the popularity of this book. In his preface to the first edition the author said "My aim in writing this book is to provide in a handy and inexpensive form a résumé of our present state of knowledge and the trend of modern research in allergy." This objective he has admirably accomplished in the third edition. The present edition differs from the previous one in that thirteen pages have been added to the text. In addition, many chapters have been revised, and new references to agranulocytic angina, parotid swellings, acne vulgaris and allergy to yeasts have been added. Each section is introduced by a paragraph of definitions followed in every instance by an excellent historical sketch in which the knowledge of the subject under discussion is traced from its earliest reference in medical literature to the present. Each clinical condition discussed is opened by a historical review followed by a concise discussion of etiology, pathology, symptoms, diagnosis, differential diagnosis and treatment. The section is usually closed by the author's digest of what has been said and his own views on the subject. His presentation of the theoretical discussions of allergy are thorough but necessarily brief. He discusses most of the important work, and the bibliography at the end of each chapter is unusually complete, especially for recent work. He has the ability to abstract the literature faithfully and invariably succeeds in presenting the main facts. His discussion of the nervous and psychic factor is excellent. The chapters dealing with allergy of the skin and especially infantile eczema are well done. He is a confirmed believer in the efficacy of hydrochloric acid by mouth in most allergic conditions, especially in the presence of hypochlorhydria. A few of the features that probably would be objectionable to most authorities working in allergy are (1) the use of "group testing," (2) the use of one syringe and needle for all intracutaneous tests (washing with saline solution after each test), (3) the use of "shotgun" mixtures in therapy, e. g., his use of "mixed inhalants solution," and (4) the presentation of the "rush method," which might conceivably lead to severe reactions and even fatalities in the hands of the inexperienced. His discussion of pollinosis is, of course, limited, owing to the presence of only tree and grass hay fever in England. One gains the impression that Bray treats his inhalant cases by

the injection of the offending allergen rather than by its removal. This is not looked on as the best method of therapy by most authorities.

Grundriss der Histologie und mikroskopischen Anatomie des Menschen: Biologie der mikroskopischen Größenordnung. Von Hans Petersen. Paper. Price, 6.90 marks. Pp. 169, with 197 illustrations. Berlin: Julius Springer, 1936.

The ground usually covered by textbooks of histology is presented in the form of a crisp enumeration of the essential facts. The order of presentation is the cell, certain methods used in routine histologic procedures, the elementary tissues, the circulatory apparatus, skeletal and muscular tissues, the skin, the nervous system (brief), sense organs, the gastrointestinal tract, the respiratory system, the serous membranes, the endocrine organs, and the excretory and genital organs. It is not a quiz compend to prepare the student for the identification of organs and tissues with minimal effort but is an account of minute anatomy from the physiologic point of view "following the tradition of German culture." The tone is highly dogmatic and there is no suggestion that anything still remains to be done in the field. It appears to be intended as a summary of more or less well established "facts" to be used in connection with a series of lectures which would take up most of the time usually allotted to minute anatomy in the medical curriculum. The illustrations are almost all line drawings with a minimum of detail. There is one colored plate with five detailed drawings and a photomicrograph.

La pression moyenne de l'homme: A l'état normal et pathologique. Par H. Vaquez et P. Gley. Paper. Price, 25 francs. Pp. 127, with 57 illustrations. Paris: Masson & Cie, 1936.

This monograph is an exposition of the principles involved in determining the mean pressure in man by the oscillographic method, together with a discussion of its significance in normal and ill individuals. The book is well suited for the reader interested in a fairly succinct exposition of the voluminous work that has appeared in the French literature concerning this method. The first part deals with the theoretical basis of oscillography, which is by and large an expansion of Marey's law. The complications induced by reflected waves in such a system are considered. The more recent work on this subject is presented as well as the theories that have been proposed recently by various French schools. One is left with the impression that some of the explanations are more complicated than they need to be. The second section deals with methodology and is clear and succinct as regards both the use of the Boullite oscillograph and the direct methods. The next section deals with the values obtained by these methods in normal individuals. The several types of oscillographs obtained are described and their cause is given. The effect of athletic training on the mean blood pressure is considered. The last section deals with the mean pressure in pathologic states, particularly hypertension, glaucoma, eclampsia, cardiac hypertrophy, hypotension, valvular defects and heart failure. Some case reports with orthodiagrams are presented. This work should be interesting to cardiologists, particularly since it represents one of the last contributions of the dean of French cardiologists, the late Prof. Henri Vaquez.

Psychology and the Social Order: An Introduction to the Dynamic Study of Social Fields. By J. F. Brown, Ph.D., Associate Professor of Psychology at the University of Kansas. Cloth. Price, \$3.50. Pp. 529, with 76 illustrations. New York & London: McGraw-Hill Book Company, Inc., 1936.

For all their intimate knowledge of the sufferings of individual members of society, physicians are often accused of lacking a broad view of social problems. Psychiatrists and psychoanalysts in particular are often said to expect of their patients radical reformations and happy adjustments regardless of the difficulties to which they may be subjected by social and economic forces. All this is natural in view of the empirical basis of the physician's practice; he is dealing with individuals, he hears of their problems and he is apt to assume that such problems are, for working purposes, to be solved by him and his patient irrespective of social laws and conditions. Nevertheless, all physicians would probably agree that the theory of medicine should never depart from its relation to science in general and hence to social science in particular but ever strive to reach a closer union with an ideal all-embracing science both

in theory and in methodology. American psychoanalysts differ from European psychoanalysts in having retained a close relationship to psychiatry and to the rest of medicine, and for this they have the commendation of other medical colleagues. But medical men in general may also suffer from isolation tendencies if not brought back occasionally to some broader concepts of the science of the human beings in the world. To the end of developing such a point of view and of showing the extent to which the affairs of the individual are determined by the affairs of the total mass of individuals, this thoughtful, carefully considered, dignified but courageous and at times startling presentation of social psychology will be for every physician not only informative but, in a sense, corrective. The author is an academic psychologist, a professor at the University of Kansas, who is carrying on research, however, with clinical subjects under medical direction, a program that will commend itself to many physicians as well as psychologists.

Medizinische Praxis: Sammlung für ärztliche Fortbildung. Herausgegeben von Prof. Dr. L. R. Grote, Leitender Arzt der Medizinischen Klinik des Rudolf-Hess-Krankenhauses, Dresden, Prof. Dr. A. Fromme, Direktor der Chirurgischen Abteilung des Stadtkrankenhauses, Dresden-Friedrichstadt, und Prof. Dr. K. Warnekros, Direktor der Staatlichen Frauenklinik zu Dresden. Band XXI: Anleitung zur Schmerzbehandlung: Kurzes Lehrbuch der Lokalanästhesie, Allgemeinnarkose und sonstiger Anwendung der Betäubungsverfahren. Von Prof. Dr. Fritz F. Härtel, Direktor der Chirurgischen Abteilung des Oskar-Ziethen-Krankenhauses, Berlin-Lichtenberg. Unter Mitwirkung von Dr. Horst Jencio. Band XXII: Infektionskrankheiten. Von Prof. Dr. Werner Schultz, dirg. Arzt am Krankenhaus, Charlottenburg-West. Paper. Price, 10 marks; 12 marks. Pp. 106, with 17 illustrations; 191, with 11 illustrations. Dresden & Leipzig: Theodor Steinkopff, 1936.

The stated purpose of this monograph is to acquaint the surgeon, particularly the beginner, with the methods of anesthesia available for various operative procedures that can be utilized by the surgeon himself without the aid of an assistant or professional anesthetist. The use of local and block anesthesia and the nonvolatile agents, such as the barbiturates and tribrom-ethanol, is therefore given primary emphasis. A brief outline of technic is given for the major nerve blocks, including the cranial nerves and their branches. The book gives a brief outline of German literature, although little reference is made to foreign contributions on the subject. It is difficult to see in this small monograph any substantial contribution either in manner of presentation or in content.

Applied Dietetics for Adults and Children in Health and Disease. By Sanford Blum, A.B., M.S., M.D., Head of Department of Pediatrics, San Francisco Polyclinic and Post Graduate School. Cloth. Price, \$4.75. Pp. 408. Philadelphia: F. A. Davis Company, 1936.

In 1931 the new "Fourth Revised and Enlarged" edition of "Practical Dietetics" by Sanford Blum had the same format and same number of pages as the previous edition and differed only by the insertion of a "Preface to the Fourth Edition" and "Vitamin Values of Foods." The latter was a one page table, inadequate as of the date of issuance, in which even the term "skimmed" milk appeared. The extent of the revision was practically indeterminable and the enlargement not discernible.

Now in 1936 appears a textbook by the same author entitled "Applied Dietetics." A careful comparison of the item with the fourth edition of "Practical Dietetics" previously mentioned reveals a close similarity. A careful check of the volume at hand in comparison with the previous opus yields conservatively the following information:

A gross increase of twenty-eight pages.

The infiltration of approximately twelve additional pages of continuity together with a new preface and with the retention of a facsimile introduction which appeared in the original (1923) and other editions of "Practical Dietetics."

Augmentation of some few food lists by one or two additional items, such as pastes, molasses candy, chocolate, port or sherry, and alcoholics. Infiltration of a few short, two line paragraphs of instructions. Recommendation of thyroid extract for weight reduction, with no comment as to its specific indication.

The word "indigestion," which physicians have studiously tried to eradicate from medical nomenclature, is to be found in diets for "Indigestion, Gastric"; "Indigestion, Chronic Gastric"; "Indigestion, Chronic, Gastric, Pyrosis"; "Indigestion, Chronic, Intestinal"; "Indigestion, Chronic"; "Indigestion, Reflex-Symptomatic."

The diabetic diets are based on foods analyzed in the uncooked state. These figures are acknowledged as being derived from the Atwater and Bryant Bulletin 28. (This bulletin is in reality a revised copy of the Atwater and Woods analyses, which were done prior to 1895. Tribute is given to Locke as an additional source for the caloric values of foods when Locke in the text "Food Values" [1911] acknowledges Bulletin 28 as his main reference.)

It is to be noted that at least on page 24 the book has kept pace with the times. Where the diet for "Anemia, Malnutrition" is now applied by way of illustration to the "business woman," in the earlier editions of "Practical Dietetics" she was classed as a stenographer.

This "new" textbook contains at least 50 per cent of the material, almost in identical form, which appeared in the first edition of "Practical Dietetics" in 1923. It is practically devoid of bibliography.

It appears indisputable that nutrition has made sufficient advances in the past thirteen years to warrant replacing the majority of the material, presented a decade ago, with the newer information. The reviewer feels that this textbook hints of misrepresentation to the physician and neither as an old or new textbook is it recommended.

A Health Education Workbook for Teachers, Parents, Nurses, and Social Workers. By Kathleen Wilkinson Wooten, M.A., Professor of Health, Georgia State College for Women, Milledgeville, Georgia. Paper. Price, \$1.50. Pp. 283. New York: A. S. Barnes & Company, Incorporated, 1936.

This workbook is complete, detailed and yet concise. A definite formula is followed for each subject presented. The presentation of each subject includes four divisions: (a) objective, (b) study outline, (c) activity, (d) references. Under study outline the problem is presented from every possible angle. Instructions on how to study the problems are given as well as suggestions for studying the problems from the local angle. Under activities the author gives specific assignments for the students. The references at the conclusion of each chapter are both complete and authoritative and include textbooks as well as magazines and pamphlets. The bibliography given at the beginning of the workbook is excellent. Only the most modern and authoritative authors' works are included. Each topic as it is presented can be given as much time as each individual teacher feels is necessary. The references are there to use, and each teacher can choose those most appealing. It is truly a workbook that can be recommended not only for teachers or those in training to become teachers but also for public health nurses and all others who have an interest in the teaching of health; and this should include those parents who are desirous of giving their children training along the lines of health without being too dependent on the school for such training.

Boomerang Leg and Yaws in Australian Aborigines. By Cecil J. Hackett, M.D., M.R.C.P., D.T.M. & H. Monograph 1. Boards. Price, 5s. Pp. 66, with 104 illustrations. London: Royal Society of Tropical Medicine & Hygiene, 1936.

After a review of literature relating to the problem, accounts are given of observations made in several localities showing correlations between a disease known as irkintja to the Aranda tribe with certain scars, between these scars and boomerang legs, and between boomerang legs and positive Wassermann reactions in the serum. Boomerang leg is the term applied to an anteroposterior curvature of the leg below the knee, the convexity being forward. Syphilis being absent from the natives, clinical observations point toward the identity of irkintja and yaws. Boomerang legs are present in all native communities examined in the Northern Territory and are reported as occurring in the northern parts of Western Australia and Queensland. Yaws is present in all areas where boomerang legs were encountered. Museum specimens indicate its prevalence also in earlier times, and early references show that yaws was present in all parts of Australia a century ago. The author believes that boomerang legs in Australia are similar to the saber tibias of yaws seen in other parts of the world.

Studies on morbid anatomy and radiography show that boomerang legs are produced as follows: The unbent tibias of early cases show changes identical with those previously

described for yaws in the Philippine Islands. Areas of rarefaction are seen in the anterior cortical shadows. The weakened bone then is deformed. Medullary lesions are indicated by thickened trabeculae. With resolution of the more acute stages the rarefied areas may clear up, leaving only the deformed bone and the thickened cortex. Then follows a stage in which the cortical thickening is resolving and the medulla of the shaft shows trabeculae. Finally the tibias may show no relative thickening in the cortex. Other bone lesions of yaws described in the monograph are multiple necrotic foci, periosteal nodes with or without necrosis, and generalized periosteal deposits. These lesions are found in individuals with boomerang legs living in communities where yaws is frequent and syphilis unknown. There are photographs of patients with boomerang legs, of skin lesions, and of bone lesions as shown in section and by x-ray examination.

Surgical Emergencies in Children. By Harold Clifford Edwards, M.S., F.R.C.S., Surgeon and Lecturer in Surgery to King's College Hospital, London. Cloth. Price, \$4.50. Pp. 274, with 99 illustrations. Baltimore: William Wood & Company, 1936.

This small book is a pithy exposition of the thoughtful conclusions of a careful and experienced worker in the surgery of childhood. It is of great interest to the practicing surgeon and a valuable guide to the pediatrician and general practitioner, but its small size precludes its use in the actual instruction in surgery. The volume is a very wise consideration of this subject. Particularly good is the section on intussusception, although it is to be regretted that mention of A. H. Montgomery's short circuiting operation in irreducible intussusception is omitted. The Orr treatment of osteomyelitis is praised. Although the tannic acid treatment of burns is adequately described, no mention is made of the Aldrich gentian violet method. The wisdom of splinting in extension to prevent burn contractures is questionable, and the author's adherence to the Sayre dressing for fractures of the clavicle might be objected to. The illustrations, while instructive, are of only second grade. The chapter on general anesthesia, by Dr. Vernon Hall, is particularly valuable. The subject matter includes pyogenic infections, fractures, injuries to muscles and tendons, acute infections of bones and joints, head injuries and inflammatory conditions of the abdomen, intestinal obstructions, congenital malformations of the intestinal tract including Meckel's diverticulum, diseases of the thoracic cavity and the urinary and genital tracts, and the ear, nose and throat, the latter by G. H. Gateman. On the whole the book can be recommended.

The Legal Aspects of Milk Control. By James A. Tobey, Dr.P.H., Fellow, American Public Health Association. Cloth. Price, \$3. Pp. 102. Chicago: International Association of Milk Dealers, 1936.

Since 1924 the author, as a public health worker and as a member of the bar, has been gathering data on the legal aspects of milk control and has made periodic reports on this subject to various interested groups. This book is an outgrowth of these studies. It contains references to, quotations from and comments on, the court decisions involving problems that have arisen in this particular field, decisions relating to pasteurization of milk, to standards for milk and dairy products, to licenses and permits, to inspection, sanitation and seizure of milk, to tuberculin testing, and to other aspects of the problem. In collating these decisions and making them readily and understandably available, as he has done in this small volume, the author has made a definite contribution to an important sector of public health work.

Selo i tuberkuloza Izdanje škole Narodnog Zdravlja u Zagrebu. [By] Miron Malojčić. [Tuberculosis in the Villages of the Sava-county (Jugoslavia). Issued by the National School of Health of Zagreb. With an English summary]. Paper. Pp. 65, with 22 illustrations. Zagreb: Stamparija "GAJ," (Lj. Filipančić), 1936.

This monograph presents the results of investigation of the prevalence of tuberculosis in the villages of Sava County in Yugoslavia. The incidence of tuberculosis amounted to from 1.8 to 6.7 per cent of the inhabitants. The greater the density and the lower the degree of hygienic culture, the larger the number of diseased. The authors express the conviction that tuberculosis in the villages is on the increase and that this increase will continue if the existing social conditions are not immediately improved.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Acts: Revocation of License for Advertisements Tending to Deceive the Public.—The board of medical examiners of California revoked the plaintiff's license to practice medicine, finding him guilty of distributing, in contravention of the medical practice act, an advertisement having a tendency to deceive the public or to impose on credulous or ignorant persons. Fuller, the plaintiff, by certiorari proceedings, contested in the superior court the action of the board. The court modified the ruling of the board by striking out the portion revoking the license and inserting in its place a reprimand to Fuller. As thus modified, the board's ruling was affirmed. Both Fuller and the board appealed to the district court of appeal, second district, division 1, California.

The board of examiners contended that the superior court had no jurisdiction to substitute a new and different penalty in the place of that pronounced by the board. With this contention, the district court of appeal agreed. Under the provisions of the California code of civil procedure, the court said, the review on certiorari cannot be extended further than to determine whether the inferior tribunal has regularly pursued its authority. The reviewing court has no authority to go beyond the question of jurisdiction, because on every other question the action of the inferior tribunal is final and conclusive. The power of the reviewing tribunal to modify, like its power to annul, can be exercised to change an action of an inferior board only when the latter by such action has exceeded its jurisdiction. In the present case, the court said, the board of medical examiners acted within its jurisdiction in imposing a judgment authorized by the medical practice act. The board alone has the power to modify or revoke it.

In his appeal, Fuller contended that there was no substantial evidence in the record to support the board's findings. The gist of the accusation against Fuller was that he published a pamphlet or booklet in which he claimed, among other things, to possess a cure for hernia without resort to the risks of major surgery. In this booklet, he asserted it to be an indisputable fact that radical surgery in the treatment of hernia results in a comparatively large proportion of actual recurrences—a return to the original condition of hernia, or to a predicament far worse than before the operation. It was further asserted that resort to surgery necessitated an open wound which might, even though under sterile conditions, become infected, whereas the injection method advocated by Fuller did not admit of any exposure to infection. The advertisement then went on to claim that Fuller injected fluid in such a manner that it did not reach the abdominal cavity and proclaimed his ability safely and economically to cure hernia without a radical surgical operation.

Without a doubt, the court said, a state has the right to require that the possessor of a license to practice medicine shall be a person of good moral character, reliable, trustworthy, and not given to deception of the public or to the practice of imposing on credulous or ignorant persons. On the other hand, the right of a licensed physician to practice is not a mere shadowy privilege, to be revoked regardless of whether the holder thereof has violated the laws of the state. It is a valuable right, to be protected at least by such safeguards as the legislature has drawn around it. The provision in the medical practice act authorizing the revocation of a license is in the nature of a penal provision and therefore it is to be construed with a degree of strictness commensurate with the severity of the penalty it imposes. Under the weight of authority, however, the reviewing court has no right on certiorari to judge the intrinsic value of the evidence, nor weigh it. The writ cannot be used to determine whether or not the evidence was sufficient, in the opinion of the reviewing court, to support the particular decision complained of, provided the inferior tribunal or board had jurisdiction and the record discloses substantial evidence to support the decision. Although, continued the district court of appeal, we might be in entire accord with the views of the court below that the penalty imposed in the present case, under all the facts

and circumstances, was out of all proportion to the element of social justice in the premises and the culpability of the petitioner, if any, under the medical practice act, nevertheless the action of the board is final and conclusive on every question except that of jurisdiction. While it was true that there was a conflict in the evidence presented to the board at the hearing, yet where the board or tribunal whose decision is sought to be reviewed has acted on a conflict of the evidence, and where it has not acted on an entire absence of any competent evidence, it has not exceeded its jurisdiction, and a reviewing court cannot, under such circumstances, interfere with or annul the decision rendered by the inferior tribunal. For these reasons, the district court of appeal modified the judgment of the superior court by striking therefrom the penalty sought to be substituted for the penalty imposed by the board of medical examiners, and, as so modified, affirmed the judgment.—*Fuller v. Board of Medical Examiners (Calif.)*, 59 P. (2d) 171.

Malpractice: Paralysis Attributed to Osteopathic Treatment.—The plaintiff sued the defendant, an osteopath, for injuries allegedly due to the latter's malpractice. The trial court sustained the defendant's motion for a nonsuit and dismissed the case. The plaintiff thereupon appealed to the Supreme Court of Colorado.

The plaintiff, a strong, able-bodied man, had a stiff neck caused by painting the ceiling of the kitchen in his house. He applied to the defendant osteopath for relief. The treatment given and its immediate results are thus described in the record: "At defendant's suggestion, he [the patient] seated himself in a chair. Defendant got behind plaintiff, put both hands on plaintiff's neck, one on each side, gave the neck a side motion once or twice, and then gave the neck a 'terrific' jerk. Instantly the plaintiff suffered a 'terrible' pain as though something in his head had given way, and as soon as the pain came the plaintiff started to vomit and became 'terribly' sick. His heart started fluttering, and after he got through vomiting defendant laid him on a table. Plaintiff completely lost his sense of balance, everything started to revolve, and he still had a 'terrible' pain in his head. His brother then came into the room, and Dr. Patton [the osteopath] said, 'I guess I was a little rough.' It seemed to plaintiff that the right side of his body had become entirely paralyzed. He could move his left arm and left leg, but had no control over the right side of his body. Defendant tried to give plaintiff a powder, but he could not swallow. He remained in defendant's office about two hours. Defendant and plaintiff's brother took plaintiff out of the office down the hall to the elevator, put him in the elevator and carried him to the brother's car, which was in front of the building. When they arrived at the brother's house, plaintiff was taken out of the car and into the house and laid in the front bedroom. Plaintiff's right side was totally paralyzed and he could not swallow. In the evening they fed plaintiff some liquid through a tube in the nose. Plaintiff's bowels and bladder absolutely stopped any movement, compelling them to catheterize him and to give him an enema."

On the second day after the treatment, the plaintiff's wife asked the defendant to summon a "medical doctor." The defendant, however, called another osteopath, who "gingerly" manipulated the plaintiff's head and left without giving the plaintiff or his attendants any information whatsoever. Subsequently, the plaintiff was removed to a hospital and there attended by a doctor of medicine. At the time of the trial, nearly three years after the osteopathic treatment, the plaintiff had no control over the muscles in his right arm, could not write or use his right arm to any advantage, the left side of his body was immune to heat, cold and pain, the sensation of touch was gone, and his eyes continued to have a "rolling motion" all the time. One of the physicians who testified at the trial said that, in his opinion, the plaintiff would never recover and that he rated him as totally and permanently disabled. One of the physicians who examined the plaintiff testified that the cause of the plaintiff's condition was a lesion of the medulla oblongata just above the junction of the brain stem and the spinal cord. This lesion, in the opinion of the witness, was due to injury, to external violence.

The trial court erred, said the Supreme Court, in holding that, because no osteopath testified concerning the method of

osteopathic treatment in similar cases, there was no prima facie showing of negligence. As applied to many cases, the rule announced by the trial court is sound, but it is not of universal application. In certain types of malpractice cases, negligence may be proved by nonexpert witnesses. Where, as in the present case, recovery of damages is sought not for negligence in making an incorrect diagnosis or in adopting the wrong standard of treatment but for the performance of an operation in a negligent manner, any pertinent evidence having a fair tendency to establish a charge of negligence is sufficient to take the case to the jury. In *Hinthorn v. Garrison*, 108 Kan. 510, 196 P. 439, a chiropractor thrust his thumb between the shoulder blades with such force and violence as to dislocate the patient's ribs. The court in that case said:

It is argued that plaintiff must prove that the defendant did not exercise ordinary skill as a chiropractor. This is correct, but the quoted part of the evidence, taken by itself, without any explanation, tends to show that a chiropractor who treated a man entirely free from any trouble with his spine, who thereafter suffered as the testimony shows the plaintiff did, must have been unskilful or careless.

So, in the present case, the plaintiff made a prima facie showing of negligence on the part of the defendant, and of a causal connection between that negligence and the plaintiff's injuries. According to the testimony, the rough treatment administered by the defendant was followed instantaneously by the plaintiff's disability. The judgment of the trial court, therefore, dismissing the plaintiff's case was reversed and the cause remanded for a new trial.—*Farrah v. Patton (Colo.)*, 59 P. (2d) 76.

Malpractice: Mistake in Diagnosis of Fracture of Hip.

—The plaintiff fell and injured his hip. The defendant, a physician, diagnosed the injury as torn ligaments and strained muscles, and prescribed rest and quiet in bed. He also directed the plaintiff's wife to rub and massage the affected area. The plaintiff remained in bed for a month or more, suffering considerable pain, but did not request that the defendant call again. During this period, however, the plaintiff's wife visited the defendant's office several times and was told that the plaintiff should continue to stay in bed, letting nature take its course in effecting recovery. Subsequently, the plaintiff obtained the services of a specialist who, with the aid of a roentgenogram, discovered that the plaintiff had an impacted fracture of the hip. An operation was performed which resulted in the plaintiff's recovery to an extent that he was able to get around with the assistance of a cane. The present suit was then filed against the defendant. The trial court sustained a demurrer to the evidence, interposed by the defendant, and the plaintiff appealed to the Supreme Court of Oklahoma.

The plaintiff's evidence, said the court, falls far short of establishing his right to recover for unskilful or negligent treatment by the defendant. The plaintiff's own expert witness, the specialist who performed the operation, testified that there are probably twenty-five different methods of treatment for a fractured hip, but that the usual method, and one quite commonly resorted to, is merely to let the patient remain in bed, permitting the fragments of the bone to knit together by nature's own healing process. This is exactly what the defendant prescribed, observed the court, though admittedly under the wrong diagnosis. The negligence on which the plaintiff's case rested consisted of the failure properly to diagnose the case, including the failure to take a roentgenogram of the injury. A mistake in diagnosis, said the court, does not constitute actionable negligence unless it is shown that the patient was injured in some manner by such erroneous diagnosis. There was no such evidence in this case. The plaintiff not only failed to offer any evidence tending to prove that any of his suffering was attributable to any act or omission of the defendant but made it affirmatively appear that the treatment rendered was in the exercise of due care according to medical practice and experience. Custom and usage are not necessarily determinative as to whether proper care was used, but they help considerably in determining that question. The burden of proof was on the plaintiff to establish the alleged negligence and the resultant injury. Since he failed to do so, it was the duty of the trial court to sustain the demurrer. The judgment of the trial court for the defendant was consequently affirmed.—*McBride v. Roy (Okla.)*, 58 P. (2d) 886.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Protective Factors in Preparation and Handling of Gold Implants and Other Radon Applicators. W. Stenstrom and C. E. Nurnberger, Minneapolis.—p. 247.

Contralateral Bronchial Infection in Pulmonary Tuberculosis.—In studying certain cases of pulmonary tuberculosis, Wu and T'ang noted that tuberculosis of one lung was not infrequently complicated by what appeared to be a more recent infection of the opposite lung. Cole and his associates in 1930 applied the term "cross-infection" to this phenomenon. The new infection would seem to be autogenous and is due apparently to the aspiration of infectious exudate and detritus from a bronchus of the earlier affected lung to that on the opposite side. The present report covers the study of 242 selected cases of pulmonary tuberculosis and several experiments on nontuberculous subjects and is intended to show that there exists in either lung a site of predilection for what the authors prefer to call "contralateral bronchial infection." It is possible that cross-infection may occur at any site in the contralateral lung, but their observations have enabled them to demonstrate that either lung has an area of predilection in which cross-infection may be expected to occur. For the right lung this area corresponds to the third of the lung lying midway between the apex and the upper margin of the middle lobe. The site of predilection for the left lung comprises one fifth of the lung field midway between the apex and the base, and in roentgenograms corresponds to the third anterior interspace. At some spot within these areas early cross-infection should be looked for, and it is frequently found that the whole of the selected

areas is diseased. Infection may pass from the left lung to the right as well as in the opposite direction. In almost 90 per cent of instances a cavity existed in the primarily affected lung. In more than 90 per cent of the cases in which it occurred, contralateral infection was found in the second interspace area of the right side and the third interspace area on the left side—the areas of predilection. Physical signs were recorded in the secondarily infected lung in less than 50 per cent of the cases. Secondary bronchial cross-infection in pulmonary tuberculosis is usually peripherally situated and involves the parenchyma of the lungs. The infectious material must therefore be aspirated into the air vesicles proper. Continued lying on the secondarily diseased side during sleep is apparently the main factor causing the drainage into the parenchyma of exudate which is present in the bronchi. It is probable that the passage of loose foreign matter from one lung to the other is largely controlled by gravity. The signs of early contralateral infection must be sought in the axillary area of the opposite lung, particularly in the absence of apical disease on the same side.

Tissue Heating Accompanying Electrosurgery: Experimental Investigation. R. D. Huntton, Iowa City.—p. 270.

Congenital Atresia of Intestine.—Martin and Elkin state that, although congenital intestinal atresia is thought to be encountered infrequently, it occurs often enough to reemphasize its importance. If congenital atresia is diagnosed early and adequate surgical treatment instituted, it is possible to avoid a fatal issue. In spite of the high mortality rate, these infants should all be given the benefit of operative intervention before dehydration, alkalosis and demineralization have occurred. The use of fluids, preferably in the form of Hartman's solution, and blood transfusions before and after operation aid in preventing shock and dehydration. The procedure carried out must vary with each individual case. Adequate exposure is necessary for complete exploration of the abdominal cavity. In the two cases reported, palliative enterostomy was the procedure of choice. In both cases, signs of complete obstruction were manifested. In the successful case this procedure was later followed by a resection of the portion of the intestine with lateral anastomosis. It became necessary to do this because chronic intussusception developed in the stoma of the ileostomy. When vomiting in the new-born becomes persistent, congenital gastro-intestinal lesions should be suspected and ruled out if the only opportunity for recovery is to be afforded the infant.

Painful Shoulder.—Ferguson presents his experiences in the treatment of the lesions of the soft tissue involving the subacromial or subdeltoid bursa and the supraspinatus tendon in 200 patients. The lesions discussed are acute traumatic bursitis, acute bursitis with calcification, subacute bursitis with calcification, chronic bursitis and tendinitis or obliterative bursitis. In spite of definite criteria on which the diagnosis of painful shoulder is made, a differential diagnosis is often difficult, as many of these lesions may be combined or may follow one another. In other instances the diagnosis may be confused by other injuries in the shoulder region, such as dislocation

of the shoulder or fracture of the greater tuberosity or of the upper humerus. In spite of these facts, however, an adequate history and a careful physical examination will, as a rule, give the examiner a fairly clear mental picture of the pathologic process with which he is dealing. The success of treatment depends in large part on an exact knowledge of the lesion. In cases in which foci of infection were found and eradicated no special benefit seemed to follow, and it has never been possible to trace etiologic relationship definitely between the painful lesions described and toxic absorption from foci of infection or from the colon. The constancy with which trauma appears in the history of patients with painful lesions of the shoulder points to the relative importance of injury as the etiologic factor in these cases.

Effect of Position of Correcting Lens on Size of Retinal Image. H. Eggers, New York.—p. 328.
Neurofibroma of Orbit: Report of Case. M. P. Motto, Cleveland.—p. 340.

Test for Aniseikonia.—Allen evolved a method of central fixation and fusion which is simple enough to use as a routine procedure in refraction and by which aniseikonia of as low a degree as 0.5 per cent is detected in some cases and differences of 1 per cent or greater are detected consistently. Most of the work was done by testing known differences in size, i. e., those created by placing concave lenses of from 0.25 to 1 diopter in power before one eye, the percentages of difference thus caused being approximately from 0.5 to 2 per cent. The apparatus used was a stereoscope fitted with rotary prisms, targets and size lenses made according to the plan evolved in the Dartmouth Medical School. The targets consist of short lines tangent to circles 6 cm. in diameter at eight points. The circles are erased and the cross lines added to aid fusion. The designs are in black and are identical, with the exception that the tangent lines in the left target are red. The correction of aniseikonia will be found most beneficial in helping the middle class of those with anisometropia, i. e., those between (1) comfortable patients with small refractive differences and (2) patients with large refractive differences who cannot possibly wear the true correction for eyes with unequal retinal images.

*Role of Anaerobic Streptococci in Human Infections. J. R. McDonald, J. C. Henthorne and L. Thompson, Rochester, Minn.—p. 230.

Cerebral Lesions in Hypoglycemia.—Baker and Lufkin studied histologically the organic lesions of the central nervous system caused by a hypoglycemia in three patients. Numerous new and old hemorrhages were found scattered irregularly throughout the three brains. These seemed most numerous in the brains of the patients who had the most severe

convulsive seizures. Extensive and widespread alterations of the ganglion cells, both the cytoplasm and the nucleus being involved, were observed, but these were due entirely to post-mortem alterations. The brains of rabbits in which repeated hypoglycemic convulsions were produced showed no cell alteration of pathologic significance.

Role of Anaerobic Streptococci in Human Infections.

—In the twenty-three cases from which McDonald and his associates recovered anaerobic streptococci at necropsy some part of the intestinal tract was involved nine times, the lung primarily seven times and the meninges four times; in three cases the lesions occurred in various tissues. Abscess of the lung was the predominant pulmonary lesion in four cases. Gangrenous appendicitis with rupture accounted for five of the intestinal lesions. There were three cases in which carcinoma of the large intestine had perforated and produced an abscess. The face in the four cases in which anaerobic streptococci were isolated from the meninges represented chronic infections in the nasopharynx, frontal sinus and middle ear. In the fourth case an infected wound in the region of the tenth thoracic vertebra had resulted in the infection. The duration of the major symptoms varied from four days up to one and a half years. In only four cases did the terminal illness last less than one week. This chronicity seems to be attributable to the low virulence of anaerobic streptococci. Microscopically, most of the lesions presented the appearance of a nonspecific chronic granuloma. Anaerobic streptococci were recovered in pure culture in eleven of the twenty-three cases. Often they were isolated both from the blood and from the lesions. They were mixed with aerobes in seven cases and with anaerobes in seven cases. In two cases the anaerobic streptococci were mixed with both aerobes and anaerobes. From three pulmonary abscesses anaerobic streptococci were recovered in association with Vincent's organisms. Bacilli of the genus *Bacteroides* were isolated with anaerobic streptococci in two cases. Of the eleven strains studied biologically, only three produced similar reactions on sugar. These three strains were isolated from cerebrospinal meningitis. All strains proved practically non-virulent for laboratory animals.

Influenzal Meningitis.—Cohn's patient had a compound depressed fracture of the skull with brain laceration and a fracture of the clavicle but recovered. This patient acquired acute influenzal meningitis five weeks after the accident. A persistent increased intracranial pressure, varying from 90 to 40 mm., was never associated with changes of the eyegrounds. After twenty-nine spinal taps and three transfusions a complete recovery without evidence of any residual manifestations ensued. Up to the time of writing the efforts to prove the efficacy of so-called immune human serum have not been satisfactory. It seems generally accepted that influenzal meningitis is a primary disease not associated with a previous infection of the respiratory tract in the majority of instances. The organism causing influenzal meningitis is immunologically type specific. Until an effective antiserum is available, repeated spinal taps, transfusions, dehydration and sedatives remain the most valuable methods of attempting to aid influenzal meningitis. The mortality remains about 96 per cent.

Significance of Obstructive Factor in Acute Appendicitis.—Wangenstein and Bowers try to evaluate the significance of the obstructive factor in the genesis of appendicitis

by experiments on animals and by careful observation of the frequency with which obstructive phenomena are noted in the spontaneous occurrence of the disease in man. In the dog complete obstruction of the infected cecal appendage was always followed by inflammation; obstruction of the washed appendage was usually well tolerated. Infection without obstruction did not produce inflammation. The essential inciting factor would appear to be a disturbance in the pressure-distention relationship of the appendix. Sustained intraluminal pressures of from 8 to 15 cm. maintained for from six to eighteen hours invariably were followed by changes in the wall of the cecal appendage. There appears to be a sphincter-like mechanism at the base of the appendix which makes of it a potential closed loop, with all its attendant inherent dangers. This mechanism accounts for the formation of appendical stones or concretions. These are laminated and are formed largely in the appendix, a sign of appendical stasis. Appendical concretions are found as acutely obstructing agents in most instances of perforated appendixes—the group in which mortality occurs. Appreciation of the significance of appendicular colic should lead to a better understanding of the nature of appendicitis. Appendicular obstruction brooks no delay and demands immediate appendectomy.

Adrenal Glands: Review of Laboratory and Clinical Studies. R. A. Cleghorn, Toronto.—p. 88.

Water-Borne Outbreak of Paratyphoid A.—Franklin and Halliday report the occurrence of thirty-seven cases of paratyphoid A among a population of 133 in the fall of 1932 at Vindex, Garrett County, Md., a coal mining settlement. In addition to the thirty-seven cases among the population there were four cases among nonresidents who contracted the disease while on a visit to the community. Identification of the causative organism was made by blood cultures, agglutination tests of serums and the isolation of *Bacillus paratyphosus* A from stool and urine specimens. The source of infection was traced to the local water supply contaminated by drainage from an outdoor privy into which had been thrown the discharges of a patient who, owing to an illness that was undiagnosed, had returned to her home from a visit to an adjoining state. Investigation revealed that eleven cases of dysentery also had occurred among the inhabitants and subsequent investigation showed that a total of twenty-seven cases of dysentery had occurred in twenty of the homes immediately preceding the outbreak of paratyphoid. It is interesting to note that an outbreak of diarrhea preceded an epidemic of paratyphoid A recorded by Berry in 1916 among the troops encamped on the Mexican border. Of 1,000 men, approximately one third contracted the infection.

*Protamine Zinc Insulin: Preliminary Observations on Its Use in Ambulatory Cases. J. M. Barsky and C. R. Levy, Wilmington.—p. 27.

Protamine Zinc Insulin.—Barsky and Levy encountered some difficulties in changing ambulatory patients from the old type of insulin to protamine zinc insulin. Undoubtedly this new form of insulin presents many advantages. The greater flexibility in the time for the administration of this insulin is of great value, but it also has increased the difficulty in ascertaining the proper dosage, since the time of administration must also be determined. In only two cases were untoward effects seen. In one the patient was awakened in the early hours of the morning by severe abdominal pains. This occurred regardless of the knowledge that the protamine insulin was being administered. Another patient was awakened with severe pain in the arms. A change in the time of administration remedied this. In the first case, however, the use of the new insulin product had to be discontinued.

Effectiveness of Oral Administration of Ephedrine in the Common Cold.—Since ephedrine has a tendency to cause psychic excitation, especially insomnia, it seemed rational to Gowen and Nedzel to combine it with a sedative such as isoamylethylbarbituric acid in the treatment of colds. Of the 566 cases studied during three years, 502 were treated in this manner and sixty-four were employed for controls (placebo treatment). The observations in the treated cases were concerned with the response to varying combinations of ephedrine and amytal. The dosage of choice proved to be one-eighth grain (0.008 Gm.) of ephedrine sulfate and three-eighths grain (0.024 Gm.) of amytal. The optimal dosage of this drug combination is considered to be six capsules or tablets daily with an interval of two hours between doses. Medication was stopped as soon as definite improvement took place, for which the number of doses varied from a minimum of one tablet or capsule to a maximum of twelve, with an average intake per person of from four to four and four tenths. The most satisfactory results were obtained

in those who reported for treatment within twenty-four hours after onset. There was evidence of improvement in 83 per cent of the treated cases, as compared to 26 per cent in the controls. Patients having fever, sore throat, cough, laryngitis and purulent nasal discharge did not respond well, nor did those who applied for treatment later than three days after the onset. The course of infection was shortened and improvement was noted earlier as compared to the various types of remedy employed by the same persons in the past. On the basis of relief, ephedrine taken orally is at least as efficacious as ephedrine applied locally, and its employment is certainly simpler.

Further Studies on Immunology of *Haemophilus Pertussis*.—Powell and Jamieson examined twenty-two pertussis cultures for virulence for mice by mixing the cultures with a certain type of starch solution prior to injection. Seven of these cultures exhibited considerable virulence for mice, killing these animals in doses of 10^{-3} cc. Sufficient virulence has been attained in this way to utilize infections established by starch-treated cultures as an index of immunity of mice to which different batches and types of pertussis vaccines have been administered. To supplement their previous immunization experiments the authors treated four additional groups of mice with additional pertussis vaccines. Of the three Sauer vaccines, the two-year-old lot and the freshly prepared lot gave a high degree of immunity, while the year-old lot gave an intermediate immunity. The Krueger undenatured bacterial antigen gave a high degree of immunity. Thus it appears that a marked immunizing capacity of pertussis vaccines can be shown by the use of white mice in the laboratory, and also that quantitative differences in immunizing effectiveness may be established.

Antirachitic Effectiveness of Viosterol, Cod Liver Oil and Percomorph Liver Oil.—In order to determine the relative effectiveness of cod liver oil, viosterol and percomorph liver oil, unit for unit, Lewis gave 365 infants 135, 435 or 870 U. S. P. (XI) units daily of one of these antirachitic agents throughout the winter months. The results of the prophylactic study did not indicate any significant difference in the effectiveness of these agents at the levels of the units employed. The degree of protection afforded by these antirachitic substances was extremely high, and only three infants among the 146 infants receiving 135 units daily developed x-ray evidences of rickets. A comparison of the curative response to cod liver oil, viosterol, percomorph liver oil and irradiated cholesterol was made in fourteen rachitic infants. These tests revealed that the daily administration of 435 units of cod liver oil, percomorph liver oil and irradiated cholesterol brought about good healing in two, four and three rachitic infants, respectively, whereas the same number of units of viosterol failed to bring about satisfactory healing in two rachitic infants. The results of the curative study, therefore, would seem to indicate that, rat unit for rat unit, vitamin D of animal source (cod liver oil, percomorph liver oil and irradiated cholesterol) is more effective in the treatment of infantile rickets than is vitamin D of plant origin (viosterol).

Lipomatosis in Insulin Injected Areas in Diabetic Boy.—Bader and Vero report their case of lipoma-like masses in a white boy, 13½ years of age, who had diabetes mellitus for four and one-half years. His diet was high in carbohydrates and low in fat. The disease has been fairly well controlled with two injections of insulin daily, one before breakfast and one before supper. The insulin requirements per day have varied between 50 and 80 units during the last two years. His blood cholesterol levels have varied within normal limits. Two years ago very small swellings were noted in the insulin-injected areas: both biceps, both buttocks and the anterior aspect of both thighs. These swellings were described as localized, edematous, symmetrically distributed tumefactions. In spite of the admonition to avoid these areas in the future, the patient continued to use them for insulin injections because "it hurt less" when these areas were used. As a result of the continuous use of these areas, the swellings have increased steadily in size. These sections show a moderate hyperkeratosis with edema of

the epidermis, portions of which appear to be slightly atrophied. The corium is somewhat edematous, the site of a slight chronic inflammatory reaction. There appears to be a moderate fibrosis of the corium. The principal feature, however, is the attached adipose tissue, which is composed of very large cells and shows evidence of encapsulation. The adipose tissue comes fairly close to the epidermis in one place, and within it one sees a hair follicle and a smooth muscle bundle, as is frequently the case when the skin atrophies. No serious sequel has been observed so far, and the lipomatous process seems to be benign. No therapy has influenced them, but a definite reduction in size can be noticed when further injections in the area are avoided.

Diet in Treatment of Anorexia.—With the thought in mind that young children on the commonly prescribed diet for celiac disease usually have very keen appetites, von Hofe considered it logical to prescribe a diet low in carbohydrates and milk free for anorexia. The response of appetite to this diet was striking; and now over a period of about ten years it has been prescribed for a considerable number of patients, with almost uniformly good results. In fact, if in a period of two weeks the result is not satisfactory, one becomes suspicious of some error in the routine. These children receive a breakfast consisting of bacon, egg, a small slice of Swedish rye bread with butter, stewed fruit and a well ripened banana. Orange juice or any other fruit juices may be included. At noon the meal consists of broth or soup (not creamed), meat, vegetables (but no potato), gelatin or stewed fruits and again a well ripened banana. For dinner the patient is given broth or soup again, vegetables, a fruit or vegetable salad, cottage cheese, one small piece of Swedish rye bread with butter, gelatin or stewed fruit and a well ripened banana. The fruits are stewed with little or no sugar. It is necessary that the mother and all others leave the child while he is having his meal. At the end of twenty minutes to a half hour the table is cleared regardless of how little has been consumed; indeed, the child should be surprised by the lack of interest. If the mother is too sympathetic and finds herself incapable of this routine, it becomes necessary to have a nurse or some intelligent relative carry out the plan. It is essential that the patient be not overtired. When he becomes ravenously hungry, carbohydrates are added in sparing amounts, and later small quantities of milk are introduced. The child is kept on a relatively low carbo-

hydrate and low milk diet for any indefinite time. Later, if the appetite wanes again, the patient is immediately placed on the original diet, but for a short period only. Loss in weight is not uncommon during the first week or two, but with the improvement in appetite this loss is soon made up. In view of the fact that the child is on a relatively low calcium diet, calcium may be administered.

Estrogen in Involution Melancholia.—Carlson performed hormone determination tests of the urine of a group of ten selected cases of depressed psychosis of the involution period. The ages ranged from 48 to 74 years, and the psychosis had existed from six months to seventeen years. The chief symptoms consisted of depression, marked anxiety, feelings of unreality, hypochondriac or nihilistic delusions and minimal mental retardation. The estrogen was determined in the urine of these women after the method of Frank. Determinations were made each week for four weeks. Five patients gave a positive reaction one week out of the four. The other five patients gave negative tests throughout the four weeks. The cases were not chosen because of the results of the tests and it is merely a coincidence that five were positive and five were negative. Ovarian activity was found to be present in one patient twenty-six years after the onset of the menopause. The other four patients had definite ovarian functions one, three, eleven and sixteen years after the onset of the menopause. A definite conclusion from these observations is that some patients suffering from involution melancholia do show some degree of ovarian activity. This evidence is contrary to previous speculations that involution melancholia is caused by a sudden cessation of production of follicular hormone or results from a nonfunctioning of the ovaries. In all patients who did give a positive test, the results were quantitatively less than those found in normal menstruating women but at the same time gave evidence of some ovarian activity. Comparison of the results of this study with the results reported in nonpsychotic women in the meno-

pause reveals an interesting similarity. In the normal menopause the urine may be negative for estrogen or it may show subnormal amounts present in varying quantities. Also it may be negative at one time and positive at another. This similarity may explain why conflicting results have been reported from the use of theelin in psychoses of the involution period. It has been suggested that the reason for failure lies in the marked variations in ovarian functions. While the study of ten cases does not permit definite conclusion, the trend of results indicates that the ovarian function in cases of menopause with depressive psychoses is found to be no different from that reported in the cases of menopause without psychoses. Endocrine changes may play a part in producing the psychosis. However, the observation that the endocrine changes were not uniform in this group of involution melancholia patients would suggest that the endocrine changes of the menopause are not the only factors concerned in the production of a psychosis. Before an endocrine basis for this psychosis can assume a major importance it must be shown wherein these patients differ endocrinologically from women in the normal menopause.

Resection of Rectosigmoid and Upper Rectum for Cancer, with End-to-End Union.—Horsley outlines a method for resection in cancer of the rectosigmoid and upper part of the rectum, with end-to-end union of the intestine, which is apparently as radical so far as permanent cure is concerned as complete evulsion of the whole rectum, while it offers the benefit of preserving the normal function of the lower part of the rectum and anus. Something more than mere existence should be included in the objectives of surgery. If the patient can be made more comfortable and life is made to seem more worth while after a procedure that offers about equal chances of cure of the cancer as other operations, this technic should be adopted. There was no operative mortality from the resection of the rectosigmoid colon with end-to-end union in the author's three cases. There was recurrence in two and the last patient has been operated on too recently to permit a claim of a cure. The first two cases were far advanced, and yet the first patient remained in good health for ten months. The second patient, whose lesion was more in the upper part of the rectum than

in the terminal sigmoid, had good health for several months. It does not appear that either of these patients would have been more likely to be cured of the cancer by a complete extirpation of the rectum. In the first patient the recurrence was chiefly above the rectum, and in the second, though no necropsy was held, there was no evidence to show that the rectum, a short stump of which was left, was seriously affected in the recurrence, and there were palpable masses in the upper part of the abdomen. While these two cases were on the borderline of inoperability, at least a few months of comfortable life resulted, which doubtless could not have been attained by any other procedure.

More Conservatism in Cesarean Section.—According to Lynch, a review of the maternal deaths recorded during 1927 and 1928 in fifteen states in the birth registration areas, made by the United States Children's Bureau, has been followed by similar compilations for cities. The observations in these mortality studies concerning cesarean section attract one's attention because the operation recently has become a common instead of a most uncommon method of operative delivery and because more than one half of the deaths following cesarean section have occurred in women who previously had borne children through the normal birth passages. Moreover, the incidence of cesarean section in these mortality studies has risen from 11 per cent in 1927 to 33 per cent in 1934. Thus cesarean section preceded 11 per cent of all puerperal deaths in or after the seventh month of pregnancy in the report of these fifteen states for 1927 and 1928. This tremendously increased incidence of cesarean section should have reduced the maternal mortality rate in the United States if the indications for the operation were sound and the mortality rate was properly low. The national maternal mortality rate, however, has remained virtually unchanged for many years. This tremendous increase in cesarean section has been initiated both by the public and by the profession—the public because of desire to escape the pain and terror of labor which it has been taught to believe is an unnecessary and unmodern thing, the profession because it feels that improvements in surgical technic must have made safe an operation the surgical mortality of which could have been considerable only in almost antediluvian time. Consequently, physicians without special training in obstetrics or in general surgery undertake cesarean section without full consciousness of the threat that their surgery entails. Its application should be limited to those cases in which valid reasons for its use exist. To achieve such consideration and consequent limitation, the American College of Surgeons should restate indications for cesarean section valid at the present time and should instruct hospitals certified by its board to permit the operation only after consultation with one of the chief obstetricians of its senior staff. Only by such means can the profession safeguard an operation that is at present a dangerous procedure.

*Occlusion of Inferior Mesenteric Vessels. L. P. Gambee, Portland, Ore.—p. 105.

Occlusion of the Inferior Mesenteric Vessels.—Gambee gives the essential processes responsible for the clinical picture produced by occlusion of the inferior mesenteric vessels. The symptom that first challenges the attention of the patient is nearly always pain of a colicky character. It may begin insidiously or it may be severe at the onset. The time of onset of the pain does not necessarily coincide with the lodgment of the embolus in the mesenteric artery. In some cases pain may not be appreciable even though a thrombus does complete the obstruction begun by an embolus. A localization of this pain in the left lower part of the abdomen along the left colon is a significant thing. It contrasts strikingly with the midabdominal pain usually associated with serious disturbances in the small intestine. The localization of pain may play a large part in differentiating occlusive vascular lesions of the superior from

those of the inferior mesentery. The next most constant symptom presented is shock. The amount of intestine involved and the rapidity with which the process develops must largely determine the degree of the shock. Vomiting in these cases is as frequent and as copious as it is in other forms of acute intestinal obstruction and is particularly significant when there is blood in it. When diarrhea and bloody stools are found with other evidence of acute intestinal obstruction, the differential diagnosis usually lies between intussusception and mesenteric vascular occlusion. Since some degree of hemorrhage is invariably found in all vascular accidents of the mesenteries, it would seem that every case in which this vascular occlusion is situated in the inferior mesentery should be accompanied by demonstrable blood in the stool. Local tenderness may indicate with some accuracy the location of the segment of infarcted intestine. Distention has been reported in from 70 to 80 per cent of the recorded cases of mesenteric vascular occlusion. The physiology of this phenomenon suggests that there is no form of acute intra-abdominal disorder which can bring on distention so rapidly as occlusion of the superior mesenteric veins. The distention that comes in the wake of infarctions in the left colon involves the colon and small intestine proximal to the infarcted area and suggests an advanced peritonitis. Leukocytosis of a polymorphonuclear type ranges between wide limits. The infarction, with hemorrhage into the peritoneal cavity, with peritonitis as well as splanchnic congestion and dehydration, is reflected in the blood count. Its chief significance in mesenteric vascular accidents arises from the fact that it is associated with a thready pulse and a subnormal temperature.

Bleeding During Early Pregnancy.—Owen states that gestation itself accounts for more than 90 per cent of vaginal bleeding in early pregnancy. Spruck observed periodic vaginal bleeding (physiologic) with no demonstrable cause in nineteen of 9,000 pregnant women. This bleeding approaching the normal menstrual flow, in both amount and duration, in only 0.05 per cent. Pathologic bleeding not directly due to pregnancy may be caused by varicose veins, hemorrhage from a polyp, fibromyomas of the cervix, cervical erosion, carcinoma of the cervix, focal endometritis with ulceration, fibromyomas and pregnancy superposed on an adenocarcinoma of the uterus. In pathologic bleeding directly due to pregnancy fifty cases of cervical pregnancy have been reported, the diagnostic triad of which consists of brisk vaginal bleeding, complete absence of uterine cramps or pelvic pain and palpation of an enlarged, pear-shaped cervix containing the embryo. Evacuation with the finger should be attempted. If cervical dilatation cannot be accomplished easily, or if the fetus is too large to remove through the partially dilated cervix, vaginal hysterotomy should be performed. Severe hemorrhage often accompanies the operation. Extra-uterine pregnancy causes the death of 1,000 women yearly in this country. Tubal pregnancy occurs once in every 300 gestations. The history of a skipped or delayed period, followed by vaginal spotting, suggests an ectopic gestation. Ectopic pregnancy occurs more often in multiparas and in women who have a scar in the iliac region. This fact suggests that these patients have had pelvic inflammatory disease or a corrective uterine operation, which may be followed by prolapse, edema or kinking of the fallopian tubes. In hydatidiform mole, a lesion of the fetal portion of the gestational sac, vaginal bleeding is the commonest complaint. The flow generally is slight, rusty and serous. Hydatidiform mole is a potentially malignant tumor. The immediate dangers are hemorrhage, perforation of the uterus and puerperal sepsis. The maternal mortality is 10 per cent. Chorionepithelioma develops in from 5 to 10 per cent of patients who have had a hydatidiform mole. About 45 per cent of chorionepitheliomas follow mole, 30 per cent follow abortion and the remainder follow ectopic gestation and labor at term.

Treatment for Chronic Leukorrhea.—Bourne and his associates considered that, if the entire mucosa of the cervix could be destroyed by one application of a chemical agent without the necessity of an anesthetic, there would be a prospect of a real cure of leukorrhea. The substance chosen was a saturated solution of zinc chloride in water. Porous clay pencils were used as the medium for introduction. They were 1½ inches long and of different diameters. If these pencils are placed in a saturated solution of zinc chloride for ten minutes, they will become fully charged with the salt and ready for use. In most cases there is no difficulty in inserting one of a suitable size without pain, and it is easy to remove by the wire passed through a hole drilled in the proximal end of the pencil. The absorption of zinc chloride by the tissues is fairly constant according to the size of the pencil and the duration of the application, and it is sufficient to produce necrosis of the mucosa extending from about 2 to 4 mm. deep. If the dose of zinc has been insufficient, either because too small a pencil has been used or because the time of application is too short, the zone of necrosis will be uneven or not deep enough to affect all the glands, and partial failure will follow; on the other hand, if the dose has been excessive, necrosis may penetrate too deeply. In these cases a large slough, representing a cast of the major part of the cervix, tunneled by its canal, may separate about the seventh day, but even though so much tissue has been removed the authors have never seen anything more than very slight bleeding at the time of separation, and in one or two cases, after removal and examination by the microscope, the canal was found to be of normal size and lined by epithelium. The type of cervix most suitable for treatment by zinc chloride is the one that has not been deeply lacerated and is therefore able to hold the pencil in close contact with its wall throughout its whole length. A strip of gauze moistened with a 5 per cent solution of sodium bicarbonate is loosely packed around the cervix and firmly against the os to maintain the pencil in position. The pencil is withdrawn in from two to four hours, depending on its size. No further treatment is necessary. The subsequent clinical course is as follows: For two or three days there is no discharge; this is due to the complete necrosis of the mucous membrane, which has not yet begun to separate as a slough. About the third or fourth day it reappears and increases until the sixth or seventh day, when a little blood is usually noticed. This corresponds to the separation of the necrotic mucosa as a slough, either in one well defined gray mass or in the form of small particles and shreds. For a few days there is a profuse seropurulent discharge, which gradually diminishes during the next four weeks, until finally there is nothing more than the normal moisture of the vagina.

Tuberculosis of Abdominal Lymphatic Glands.—From 1923 to 1932 Colt and Clark saw 239 cases of tuberculous disease of the abdominal lymph glands. Thirty-eight patients with caseous mesenteric glands were operated on, some of them for unrelated conditions, during acute obstruction or for acute appendicitis. Roentgen examination was made in eighteen cases and, in eleven, areas of calcification were seen suggestive of glands that had calcified or had begun to calcify. Many of these patients were admitted as cases of acute or subacute appendicitis and the figures show that the two conditions frequently coexist. In twenty-nine of the thirty-eight cases it was possible to excise the affected glands. From the suggested relationship between a diseased appendix and caseation it seems that the appendix should generally be removed. From a study of the 201 consecutive cases of calcareous mesenteric glands it seems that during a period of from a few months to a year or more each caseous and calcifying gland may be a source of danger. This does not necessarily correspond with the period during which the patient is actually in danger. One or two glands may caseate and commence to calcify. Others may break down some considerable time after the first. The cycle is gone through again with another danger period to the patient. There is no doubt about this happening, as in some of the cases caseous glands coexisted with calcified glands. That a natural cure by complete calcification occurs in a large proportion of cases must be obvious. That tuberculous disease of the mesenteric glands does embarrass the absorption of fat is undoubted. In a number of cases, calcareous glands are present in the abdomen without giving rise to any complaint whatever. In others, apart from some slight tenderness and hyperesthesia in the right lower quadrant of the abdomen or the umbilical region, there may be no other physical sign to be made out. There may be some rigidity in the right iliac fossa. There is usually some distention of the abdomen, which may be more marked during attacks of pain. Roentgen examination of the abdomen is generally conclusive. Of the 166 cases in which operation was required, twenty-two were untraced. In thirty-five of the 201 cases, reoperation was required; three patients died shortly after operation, two of them having been admitted with acute obstruction and the third being in a very obese woman whose wound burst nine days after the removal of a chronically inflamed appendix and of a few calcareous glands and the freeing of some light adhesions. Recent general peritonitis was present; the cause of which was not apparent at postmortem. The fourth death occurred from mitral stenosis two years after postoperative hemiplegia. Of the remaining 163 cases, 144 were traced and the results were found to be excellent in 109, good in seventeen, poor in six and bad in eight.

Nevocarcinoma of Skin and Mucous Membranes.—In their analysis of twenty-five cases of nevocarcinoma admitted to the Middlesex Hospital during 1928 to and through 1935, together with some cases of benign melanomas, Williams and Martin correlate the histologic and clinical types with prognosis and emphasize the clinical features. Pack, quoted by Adair (1936), in a careful clinical investigation found that every individual has at least twenty pigmented spots on his person. These spots are important for two reasons—they may cause disfigurement or become malignant. The authors' five patients having undoubted "congenital" nevocarcinoma are alive and well without recurrence, one for five years, three for two years

and one for one year after treatment. Of the twenty "acquired cases," fifteen are dead. Of the five patients who are still alive, the survival rate is one for seven years, one for six years, two for four years and one for two years. In two of these patients, recurrences occurred in the first year after treatment and received yet more radical surgical treatment. The review has impressed on the authors that improvement in results can be achieved only by the removal with a scalpel of outgrowing pigmented congenital tumors exposed to friction by shoes, clothing or toilet. The original tumor has been known to double its size within forty-eight hours and the disease should be included among the "surgical emergencies." However small the primary lesion, a wide excision with at least 2 inches of normal skin, together with an extensive radical dissection of the lymphatic glands and fascia is essential. When this necessitates amputation of a limb, it should be advised without hesitation. A full carcinoma-lethal dose of x-rays should be applied in all cases, and even when radical surgery is possible this course of treatment should be given as a postoperative measure.

Fuchs Serum Proteolysis Test for Malignancy.—Woodhouse examined 170 serums by the Fuchs proteolysis method, and up to the present the diagnosis in 120 is sufficiently established (usually by operation, histologic or postmortem examination) for comparison with the serum reaction. In fifty-three malignant cases examined by the Fuchs proteolysis test, correct results were obtained in fifty. The test also gave correct results in thirty-eight of forty-two nonmalignant cases. The serum from patients who had previously received irradiation gave negative reactions to normal protein in almost every instance.

 *Mechanism of Visceral Pain. H. J. Wilkinson.—p. 48.
 Funny Turns. S. O. Cowen.—p. 58.

Mechanism of Visceral Pain.—Wilkinson has discovered the painful area in visceral pain by detecting an area of skin that appeared to him to be cooler to the touch. He first observed this in a patient complaining of epigastric pain. When he placed his hand on this region there was a spot that felt definitely cooler to the touch than the surrounding areas. Normal stimulation of the visceral afferents merely causes reflex changes in the intestine; there are no well defined alterations of consciousness and there are certainly no sensations of pain. More violent stimulation of the intestine leads to increased bombardment of the sympathetic nuclei in the lateral cornu of the cord, with the result that the impulses pass over not only into those neurons ultimately connected with the intestine but also into adjacent vasomotor neurons that innervate the peripheral vessels. This causes vasoconstriction and associated conditions in these areas, thus providing the adequate stimuli for the pain nerve endings. Pain impulses thus arise in these superficial somatic areas and pass by way of the posterior root ganglions into the cord and thence by way of the secondary neurons of the pain path, the fibers of which run in the posterior spinothalamic tract to the thalamus and then on to the cortex. When this occurs, sensations of pain are experienced. Briefly, the visceral afferents, when adequately stimulated, cause reflex vasoconstriction in the somatic peripheral structures, and conditions thus arise which lead to stimulation of the pain endings and to the production of pain sensations. The pain is thus felt in the somatic tissue not because it is merely "referred" but because the pain nerves are actually stimulated here. The lowering of the skin temperature is merely a manifestation of the vasoconstriction and associated phenomena which provide the adequate stimulation for pain impulses and is not to be regarded as the cause of the pain. The pain occurs merely approximately in the midline because, owing to the anastomoses of the vessels, it is in the midline that the phenomena will be most intense. This mechanism also explains why a pain is sometimes felt in the back; in fact, the pain in the back is in some cases the only pain felt. Further, the combined sensations of pain in the anterior abdominal wall and in the back may

give rise to the judgment of the pain as being deep seated. When the pain is felt only in the midline and a "cool" spot is identified and infiltrated with procaine hydrochloride, the pain appears to "migrate" to another part of the segment involved. This is due to the fact that the patient experiences only the more intense pain and, when this is abolished, the less intense pain, if it exists, is felt in another part

Thyroidectomy in Nonexophthalmic Cardiac Insufficiency and Angina Pectoris.—Spurred by the recent communication of Santy and Bérard, Lian and his associates describe their own observations following total thyroidectomies which they performed on three patients with cardiac insufficiency, but with a normal thyroid, two patients with mitral and aortic disorders in connection with cardiac insufficiency and three patients with angina pectoris with cardio-aortic lesions. The first three patients show no discomfort from their slight thyroid insufficiency, except for some chilliness and some increase in weight. They all take small quantities of digitalis. The first patient with the mitral disorder had an aortic insufficiency and complete arrhythmia which developed a few months after the operation, to which were later added other disturbances, including loss of psychic equilibrium. After some stay in the country her condition improved, but she died suddenly nine months after the operation. In the second mitral patient there was loss of dyspnea on exertion, but the liver remained large, and chilliness, bloating and some apathy followed in the wake of the operation. The cardiac insufficiency returned and the fatal end was precipitated by severe dyspnea. After the thyroidectomy the first patient with angina pectoris could be somewhat on her feet, but she also soon became depressed and edematous and later mentally deranged. At necropsy the coronary arteries were found to be completely obliterated. The second angina patient enjoyed good health for three months after the operation but later on had about two attacks of angina daily and died from coronary atheroma. The third patient with angina pectoris was an obese woman who had dyspnea on exertion. After the operation one grave attack of dyspnea could be checked by a small injection of thyroid extract. The patient continues to have attacks of angina and her sleep is disturbed by difficult breathing. The lesson drawn by the authors is that subtotal thyroidectomy would have given much better results, especially if the patients had been operated on at an earlier stage of their disease.

Action of Phrenicectomy on Bronchopulmonary Secretions: Its Mechanism. C. Bibicescu and G. Polatos.—p. 190.

Selenium Poisoning and Pellagra.—According to de Rohan-Barondes, selenium is encountered in the human body under certain abnormal conditions. Selenium alkalis and oxides are toxic. Its oxide given orally in minute quantities seems to contribute to the oxidation of the body sulfur. It is used for this reason in the treatment of cancer. Animals fed on plants rich in selenium become paralytic and die from "blind staggers," and the U. S. Department of Agriculture recommends the saturation of the soil with sulfur. Comparison of the symptoms of selenium poisoning with those of pellagra shows that the gastro-intestinal disorders and the mental and nervous derangements are identical in the two diseases and that the same skin symptoms occur in the two when the patients are exposed to strong light. Typical symptoms of pellagra have been observed in alcoholic patients who drink cheap beverages made

of corn probably containing too much selenium. A diet rich in sulfur and yeast seems to have an immunizing effect on selenium toxicosis. But in cases in which the liver and the gastro-intestinal tract have been exposed to too much damage this diet will probably be of little use. It is necessary to examine chemically and spectroscopically all food coming from plants growing in pellagra regions. Even if the ingested quantity is small, its long continued intake is likely to lead to accumulation and severe toxicosis, especially in persons with low tolerance.

Some Particulars in Contralateral Pneumothorax. E. Libert.—p. 1200.

Value of Negative Tuberculin Reactions.—Coulaud states that the majority of phthisiologists maintain that there is no tuberculosis when the BCG reaction is negative. Yet the facts militate against this assertion and neither the value of the cutaneous nor that of the intradermal reaction can be absolute. About thirteen years ago he reported a method of imparting a slowly progressive tuberculosis to the rabbit, which even after many years showed no positive tuberculin reaction. Calmette, having vaccinated cattle with BCG and believing them to be cured, had them slaughtered and was surprised to find caseous mesenteric nodes containing live Koch bacilli. Observations of temporary anergy have been made after grip or measles or at the end of gestation. In the life of women it is the onset of new phases, such as puberty, menstruation, pregnancy and the menopause, which are characterized by a physiologic hyperthyroidism which causes an eclipse of the allergic reaction. Thyroid treatment often subdues tuberculin reactions, while ovarian treatment enhances them. Anergic young women may even be made allergic by ovarian treatment. In thousands of cutaneous reactions the author found that they were negative in women who had undergone ovariectomy or appendectomy. The allergic state is by no means consistent and unchangeable. Any reinfection or discharge of endogenous bacilli may modify the tuberculin reaction. On a former occasion the author made subcutaneous injections of BCG in allergic patients, expecting the tuberculin reactions to become stronger. The reactions were not only modified but were even weakened in the majority of cases. Furthermore, all kinds of factors, known and unknown, may temporarily or permanently modify the allergic intensity. He feels that his deductions have value only for a populous center, such as Paris. People living in open spaces or in northern countries may not have come in contact with tuberculosis.

Creosote in Pleural Irrigations.—Arnaud and his collaborators made the observation that the draining of tuberculous pleurisies with effusion is often but a first step leading to thoracoplasty. Therefore they were justified in attempting irrigation first and, after having tried other medicaments, they used in one case a 10 per cent solution of creosote in alcohol. During the following hours the temperature fell from 102.5 to 98.5 F. Three further irrigations were given at intervals of two days, and after every irrigation 300 cc. of the solution was left in the pleural cavity. Cultures of the pleural fluid soon were sterile. Two weeks later the temperature rose again to 105 F. and pneumococci were observed in the culture but were of little virulence. A new irrigation of creosote solution proved itself immediately effective: there was a strong fibrinous reaction and a considerable diminution of pneumococci. Similar observations were made in two other cases with even better results. To trace the effects of creosote solutions on purulent pleurisies the authors mixed one drop of creosote with a variable number of drops of young culture in bouillon so as to obtain mixtures of from 0.1 to 0.01. These creosote cultures were put into the incubator for from three to twenty-four hours and then recultured. Only the 0.01 cultures were not sterile after a contact of six hours. Creosote is naturally

injurious to the skin, but it is well tolerated by the pleura, especially when the pleura is thick. The elimination of the creosote could not be followed up. The amount of phenol derivatives in the urine was insignificant. No kidney trouble resulted.

*Phenols in Blood in Uremia: Technic for Determination. F. Marcolongo.—p. 83.

Lithiasis of Salivary Gland: Case. O. Salico.—p. 91.

Technic for Determination of Phenols in Blood.—Marcolongo points out the disadvantages of present methods for the determination of phenols in blood in uremia. He describes a new colorimetric micromethod to demonstrate ether soluble and ether insoluble volatile phenols in blood. The apparatus used is of Becher's type. The technic is as follows: Five or 10 cc. of blood is made uncoagulable and put in a glass beaker of 1 liter capacity with 200 cc. of distilled water, 2 Gm. of sodium bicarbonate and 2 Gm. of sodium sulfate. The mixture is vigorously stirred and distilled. The first distillate (free phenols) is obtained in a quantity of 100 or 150 cc. The solution remaining in the beaker is allowed to cool. Water is added to the same amount (100 or 150 cc.) as that obtained by distillation, as well as 2 cc. of concentrated sulfuric acid. Distillation is then repeated. The second distillate (bound phenols) is obtained in a quantity of 100 or 150 cc. The distillates are subjected separately to the process of removal of the phenols by ether. The ethereal phenol extracts, separately, are neutralized and concentrated by evaporation of ether to a volume of 15 cc., to which 5 cc. of distilled water is added. The aqueous residues from the two distillates are mixed and concentrated in an electric oven from a total volume of 200 cc. to 40 cc. The colorimetric Moir test is then performed, separately, on 40 cc. of the mixture of equal parts of the two aqueous ethereal phenol extracts and on 40 cc. of the concentrated aqueous residue from both distillates. Positive and strongly positive results of the reaction are shown by the appearance of orange-red and red respectively. The intensity of the color is reached in fifteen or thirty minutes. Negative results of the test are shown by the appearance of a greenish yellow. The control solutions for colorimetry are prepared by diluting, in distilled water, a 1 per thousand phenol solution in tenth normal hydrochloric acid so that 20 cc. of each control solution contains 0.0125 and 0.025 mg. of phenol respectively. The solution used in the test is that of the closest color to the unknown one. For lighter colors, such as those given by the residues of the distillates, 20 cc. of the control solution containing 0.025 mg. of phenol is brought to a volume of 40 cc. by adding distilled water to it. Extremely weak phenol solutions containing 0.005 mg. of phenol in 20 cc. of the solution give a greenish yellow which correspond to negative results of the Moir test. The colorimetry is made within fifteen to thirty minutes of the appearance of the color. Final calculations of colorimetry are made in the usual way: The figure given in the colorimetric scale by the control solution used is divided by that given by the solution of unknown phenol content and the result is multiplied by the figure that shows the concentration of the original control solution used (either 0.0125 or 0.025). The result is then multiplied by 10 or 20, depending on whether 10 or 5 cc. of blood was used in the test. The final figures indicate the phenol contents in milligrams per hundred cubic centimeters of blood. The advantages of the method described by the author are the following: The amount of blood used is small. The technic is easy and results are obtained within an hour. The colorimetric reaction is not subject to errors. The test is of relative precision, sensitivity and specificity. Substances other than phenols, the presence of which may render uncertain the results of the test, are eliminated by the process of etherization. The loss of phenols during the procedure is small and one is able to determine the presence and amount of both ether soluble and insoluble phenols. The amount of insoluble phenols in the blood is small. The importance and significance of the latter will be discussed further by the author.

Adhesive Mediastinal Pleuritis: Pathogenic, Clinical and Statistical Study. R. Rimini.—p. 42.

Experimental Tuberculous Cerebral Meningitis. E. Zamboni.—p. 56.

Inducing Exudative Pleurisy.—Gunella states that exudative pleurisy, spontaneously developed in the course of artificial pneumothorax, has a favorable action on the latter in certain cases of unilateral pulmonary tuberculosis. In bilateral tuberculosis it has a favorable action on the tuberculous lesions of the pleuritic side but an unfavorable action on those of the contralateral side. The author discusses the advisability and indications of inducing exudative pleuritis. The latter is a complication of pneumothorax, its beneficial effects are restricted to few cases and, spontaneously developed or artificially induced, it may be followed by more or less grave immediate or late complications. Induction of exudative pleurisy is indicated only in unilateral pulmonary tuberculosis on the following premises: when total or subtotal pneumothorax fails to close the cavities and in the presence of intractable adhesions that prevent collapse, especially if there is hemoptysis. In both cases induction of exudative pleuritis will be resorted to if the adhesions are beyond reach of the Jacobea's resection, when phrenic-coxeresis or partial thoracoplasty is not indicated and when the results of any of these operations are unsatisfactory. Otherwise it is advisable to prefer the operations rather than induction of exudative pleuritis.

*Primary Actinomycosis of Fallopian Tubes. G. De Faria and A. Fialho.—p. 1.

Female Obesity According to Conceptions of Constitutionalist School. T. Botelho.—p. 25.

Primary Actinomycosis of Fallopian Tubes.—According to De Faria and Fialho, only two cases of tubal actinomycosis out of a total of seventy-nine cases of actinomycosis of the genitalia are reported in the literature. The authors' case is the first reported in Brazil and the third reported in the literature. The diagnosis of genital actinomycosis is made, as a rule, by microscopic examination of the involved organ which has been surgically removed. The infection takes place through the digestive tract and sometimes through the blood. Puerperium and lactation stimulate the condition to a malignant evolution. The treatment consists in early operation with removal of involved organs before rupture of the tumors with consequent dissemination of the infection. In the case reported a preoperative pathogenic diagnosis was not made. The purulent secretion of the vagina failed to show the fungi on microscopic examination. The disease evolved, simulating adnexitis. The treatment was bilateral salpingectomy followed by drainage and administration of sodium iodide intravenously. On microscopic examination the tubes were found to be the seat of infiltration and other changes of the mucosa. The tubal tumors contained mycelia and actinomycotic granulations. The recovery of the patient was verified three years later.

Prontosil in Treatment of Erysipelas and Simultaneously Existing Renal Disease. A. Virgil, I. Pascal and V. Lăzărescu.—p. 203.

Ion Concentration in Allergic-Hyperergic Inflammation.—Knepper, after directing attention to Schade's observation that inflammation is usually accompanied by an acidosis of the tissues, that is, by an increase in the hydrogen ions,

suggests that, since allergic-hyperergic inflammation differs in many respects from normo-ergic inflammation, it differs also with regard to the molecular disturbance. He determined the ion concentration in allergic-hyperergic infiltrates and found that this type of inflammation is not accompanied by a tissue acidosis but presents alkaline values. He shows that this observation has not only theoretical but also practical therapeutic significance. Calcium is often given in allergic disorders and effects a change toward acidosis. The author suggests that the therapeutic effect of calcium is probably exerted by way of this acidosis and not merely by reducing the permeability of the vessels. He thinks that in rheumatism, which is also considered an allergic-hyperergic inflammation, salicylic acid and other antirheumatics act by inducing tissue acidosis.

Question of Neurogenic Hypertension.—Schneyer points out that in animals it is possible to produce an arterial hypertension by the exclusion of some of the pressoreceptor circulatory nerves. Reasoning that clinical studies on whether a corresponding form of hypertension exists in human subjects would throw light on some disputed questions in the problem of hypertension, the author made observations on 224 patients with hypertension and on ninety persons of the same age groups but without hypertension. The results of studies on the relationship between blood pressure and the pulse rate, of the carotid pressure test and of other investigations justified the assumption that there is no neurogenic hypertension in human subjects that corresponds to the hypertension resulting from the exclusion of pressure nerves in animals. Moreover, there is evidence that the hypertension which in animals follows the exclusion of the pressor nerves is not permanent but subsides again.

*Positive Aschheim-Zondek Reaction in Tuberculous Disease of Uterine Tubes. A. von Latzka.—p. 277.

Determination of Pregnancy by Means of Infusoria.—Kustallow mentions the different pregnancy reactions and then points out that he himself aimed to find a test object that would permit a correct and rapid determination of pregnancy. He attached especial importance to the results in ectopic pregnancy. As test object he employed infusoria, namely, *Ciliata paramecium-caudatum*. He places a drop of hay solution with infusoria on a slide (without coverglass) and examines it under the microscope, which reveals that the animalcules move rapidly in straight lines. Then he adds a drop of catheter urine. If the urine is from a pregnant woman, the animalcules commence to move around their longitudinal and transverse axis and become grouped in piles (a sort of agglutination). They have a tendency to move toward the periphery, and after from thirty to ninety seconds complete cessation of all movements usually results. Shortly before movement stops, some of the animalcules undergo destruction: first, a rocket with a fanlike projection protrudes from the posterior pole of the body; this is followed by complete disintegration into small granules. If movements persist beyond ninety or 120 seconds, the reaction is incomplete; if they persist longer than five minutes, it is negative. In many cases of ectopic pregnancy, the cessation of movement requires up to two minutes. The reaction is positive also in case of abortion as long as there are still pregnancy products in the organism. Investigations on what substances are responsible for the action exerted by pregnancy urine on infusoria convinced the author that proteins, lipoids, carbohydrates and perhaps hormones play a part. The author emphasizes the simplicity and rapidity of the method and the fact that at least in ectopic pregnancy it has a greater degree of correctness than do other methods; he also points out that the test is still in the experimental stage.

Positive Aschheim-Zondek Reaction in Tuberculous Disease of Uterine Tubes.—In discussing the factors that are responsible for the production of the Aschheim-Zondek

reaction, von Latzka mentions various conditions other than pregnancy that cause an increase of the gonadotropic hormone in the urine. Among others he mentions tuberculous disease of the uterine tubes, pointing out that Wilson observed a positive Aschheim-Zondek reaction in such cases. He himself observed two cases that corroborate Wilson's observation. He describes these cases and shows that cases of threatening perforation, as the result of adhesions, of positive Aschheim-Zondek reaction and of menstrual disturbances may readily be mistaken for extra-uterine pregnancy. A definite differentiation is possible only by laparotomy.

Treatment of Adrenal Insufficiency. K. Hitzengerber.—p. 197.

Treatment of Fracture of Spinous Processes.—Schnek points out that avulsion of the spinous process of the seventh cervical vertebra or of the spinous processes of the neighboring vertebrae is relatively frequent in road and dam construction work, in certain types of agricultural work and in some sports. This type of fracture results usually from a sudden, jerking muscular traction. Only conservative methods of treatment are advisable. Surgical intervention is not required during the early or during the late stage. The pain in the surrounding musculature is due to the sensitivity of the site of fracture. The author recommends anesthetization by means of from 5 to 10 cc. of a 2 per cent solution of procaine hydrochloride. If after a few minutes the pain has disappeared, all movements are possible again but if, during the following days, the surrounding musculature still remains sensitive, he advises infiltration with a 0.5 per cent solution of procaine hydrochloride. The patients are usually able to work again after about six weeks. There is no permanent impairment.

*Symptoms and Pathogenesis of Ludwig's Angina. M. B. Fabrikant.—p. 241.

Perforating Gastroduodenal Ulcers.—According to Lemberg there were 233 cases of perforation of gastroduodenal ulcer in which operation was performed at the Emergency Institute of Leningrad from 1932 to 1935. There were 222 men and eleven women. In twenty-nine cases (12.4 per cent) there was no history of ulcer symptoms in the past or prior to the attack. Thirty-three (28.6 per cent) manifested exacerbation of the symptoms in the days preceding the perforation. Sudden onset of severe epigastric pain, absence of abdominal breathing, rigidity of the abdominal wall and pneumoperitoneum constituted the most reliable diagnostic signs. Treatment consisted of a simple suture of the perforation in two layers, the omentum being utilized to protect the suture line, and closure of the abdomen without drainage. When the perforation was located in the pylorus or in the duodenum, a gastro-enterostomy was added. The mortality was 16.7 per cent. The author is opposed to partial gastric resection on the ground that wide application of it would result in high mortality. He is not convinced that resection is the best form of treatment for every type of ulcer. The author believes that the fact that Yudin was able to show the low mortality of 9.8 per cent in 673 resections is due to selection of cases; otherwise it would be difficult to explain the same author's 53.4 per cent mortality from simple suture. He concludes that the palliative procedure of simple closure with

or without gastro-enterostomy is capable of saving many lives and of curing a fairly high proportion of cases. Patients with late ulcer symptoms following palliative procedure may be subjected to a medical regimen or to a resection under much more favorable conditions.

Ludwig's Angina.—According to Fabrikant, Ludwig's angina is not a specific clinical entity. It is due to the action of anaerobic micro-organisms. The infection spreads rapidly along the floor of the mouth to reach the retropharyngeal space. The infection is characterized by a rapid spread, woody infiltration without definite limitation, lack of involvement of the overlying skin, at least in the beginning, marked edema of the mucous membrane of the floor of the mouth, lifting the tongue upward and backward, and symptoms of general intoxication. The various submaxillary, submental, sublingual and retromaxillary abscesses, lymphadenitis and periadenitis are to be distinguished from Ludwig's angina by the fact that they break down early and form pus. In Ludwig's angina there is formed early in its course a dirty gray infiltration of the muscles with the formation of a small amount of ichorous fluid having a marked gangrenous odor and at times containing gas. Bacteriologic studies have revealed many organisms, such as staphylococci and hemolytic streptococci. The author believes that the anaerobes are the important organisms in the process. The most frequently found organism in their cases was *Bacillus perfringens*. Early recognition and immediate operation are essential if the patient is to be saved. The author recommends a transverse incision parallel to the jaw, division of the muscles, excision of gangrenous tissue and wide exposure down to the root of the tongue. The wound is dressed twice daily and is irrigated with hydrogen peroxide. The author treated eleven patients at the stomatologic institute of Kharkov with one fatality.

Significance of Structural Analysis in Biology. L. Einarsen.—p. 1.
*Total Volvulus of Stomach: Case. E. Tølbøll.—p. 14.

Total Volvulus of Stomach.—Tølbøll believes that his case of torsion about both the longitudinal and the transverse axis in a woman, aged 43, is the first Danish case of total volvulus of the stomach. He says that in this disorder there is a change of position of the stomach with a twisting of about 180 degrees about the longitudinal or the transverse axis. In partial torsion only part of the stomach turns about the transverse axis; in total torsion there is a turning of fully 180 degrees about the longitudinal axis, which may be complicated by a secondary torsion about the transverse axis. The idiopathic form, always total, includes all cases without pathologic changes in the stomach, presumably because only the sound stomach can perform such marked shiftings in localization. In the symptomatic form, always partial, pathologic gastric or perigastric conditions are present. This form, far more frequent than the idiopathic, always affects the pyloric horizontal part of the stomach. While the pathologic changes often explain the mechanics of partial torsion, the origin of total volvulus is especially difficult to account for. Gastroparesis and hypermobility are regarded as predisposing factors. Diagnosis in total volvulus is difficult in spite of several characteristic signs—violent vomiting, vomited matter never mixed with bile or feculent, rapid cessation of vomiting followed by spitting up of regurgitating mucus from the esophagus, the patient's inability to take a particle of food, development of meteorism localized to the upper left part of the epigastrium and at first limited to this region, remarkably slight tenderness of the epigastric tumor in view of the violence of the disturbance, and finally cardiac obstruction making introduction of the stomach sound impossible. The last-named condition is of great significance if the presence of a foreign body in the esophagus is excluded but may fail in the milder cases without torsion about the transverse axis. Treatment, as soon as possible, is surgical. The symptoms in partial volvulus are less pronounced, but there are violent vomiting and intense pain in the epigastrium, which may disappear as suddenly as they set in, when the torsion ceases. Even though the danger passes for the time, omission of intervention is risky, as the prognosis in partial volvulus also is doubtful. Roentgen examination is as important and decisive in partial volvulus, in which

the diagnosis is hardly possible without its aid, as it is difficult and uncertain in total volvulus. Thirty-three cases of total volvulus were reported up to 1926. Of the thirty-four cases, including the author's personal case, necropsy was done in the ten cases in which operation was not performed. In six of the remaining cases death followed the operation and in eighteen there was recovery. Diagnosis was made before operation in five cases. Most cases occurred in adults, aged from 40 to 70, but two cases are recorded in children aged respectively 2 (Siegel) and 5 (Dujon) years.

*Hematologic Study of Some Cases of Chronic Nephritis. N. G. Nordenson.—p. 1.

Chronic Nephritis.—Nordenson discusses eighteen cases of anemia in which all degrees were represented, from those with 4.26 million red blood corpuscles and a hemoglobin value of 82 per cent to grave cases of 1.44 million red blood corpuscles and a hemoglobin percentage of 29; it was usually of secondary type with index below 1. He says that no regenerative changes in the form of reticulosis appeared in the peripheral blood. In no case were there marked signs of degeneration in the red blood corpuscles. There was pronounced granulocytosis in all but one case. Intravital examination of the sternal bone marrow revealed elective injury of the erythropoiesis; the leukopoiesis was relatively intact. The percentual relation between the number of white blood corpuscles and the nucleated red blood corpuscles was reduced in almost all cases. While the erythrocytic elements normally constitute from 20 to 25 per cent of all cells in the sternal punctate, the average in this material was 13 per cent. The bone marrow was comparatively intact in two of the three cases in which treatment with iron was fairly successful and in the one in which a blood transfusion gave good reaction. The author concludes that the anemia in chronic nephritis depends on a reduced bone marrow function caused by a beginning aplasia of the erythropoietic system. Necropsy in eleven of the cases showed the normally active bone marrow to be unusually pale. Both anatomic and histologic changes indicated a lessened regenerative power. In a number of cases a certain parallel appeared between the renal and renal function on the one hand and the anemia on the other, and, on the whole, the longer the duration of the nephritis, the more marked was the anemia. To what extent other factors act in the genesis of the beginning aplasia of the erythropoietic system is uncertain.

*Weil's Disease: Three Cases. I. Knudsen.—p. 62.
Casuistic Report on Treatment of Pneumonia with Quinine Urethane Calcium. C. C. Jacobsen.—p. 64.

Sequels After Trauma of Cranium.—Busch and his associates discuss six posttraumatic syndromes; namely, epidural hematoma, depression fractures, traumatic arachnoiditis, circumscribed traumatic brain lesion, traumatic diploe-osteomyelitis and traumatic cephalalgia, each illustrated by a verified case from the neurosurgical clinic of the Rigshospital. The syndromes are typical with regard to etiology, pathologic anatomy and symptomatology and have a favorable prognosis provided the disorder is recognized and proper treatment is instituted, and so common and of such significance that they are of interest not only for the specialist but also for the practitioner, whose knowledge of these cases will in many instances decide the fate of the patient.

Weil's Disease.—Knudsen reports three cases of Weil's disease. The first two patients were farmers, aged 52 and 65, who after a heavy rain had spent two or three days in cleaning their blocked sewers, assumed to have been infected by rats. The third patient, aged 27, had for three weeks been working in water up to his waist, cleaning drainage ditches, and is regarded as supporting the theory of the primary occurrence of spirochetes in muddy water and their growth in it during summer weather.

SIGNIFICANCE OF THE TUBERCULIN TEST

F. E. HARRINGTON, M.D.

J. ARTHUR MYERS, M.D.

AND

N. M. LEVINE, M.D.

MINNEAPOLIS

The incidence of positive reactors to tuberculin among the children and young adults is the best criterion of the tuberculosis problem in any community. It is far superior to mortality rates, since many persons who have tuberculosis die of other causes and the death certificates do not record the coexisting tuberculosis. One has only to consult postmortem records to obtain abundant evidence of this fact. Moreover, the morbidity rate does not approach the accuracy of the tuberculin test as a criterion of the tuberculosis problem, since, in approximately 80 per cent of patients, symptoms are a late manifestation and do not bring patients to physicians for diagnosis until the disease is well advanced. Indeed, there is an average period of approximately two and one-half years before symptoms appear during which the disease can be located by modern methods. In most cases there is a much longer period after the tuberculin test is positive before there is any evidence of disease on the x-ray film.

In 1926 we¹ published the results of tuberculin testing among school children in the city of Minneapolis, which showed that, of 2,118 tested, 47.33 per cent reacted positively. In the ten years that has passed since this work was done, much effort has been put forth and large sums of money have been spent to protect girls and boys against contamination with tubercle bacilli. While a good pasteurization ordinance was in effect in 1926, considerable milk that was not pasteurized was consumed by children, particularly when they were out of the city on vacations, and like instances. The pasteurization ordinance has continued in effect during the past ten years and in addition tuberculin testing of cattle has gone forward until the state of Minnesota has been accredited with reference to tuberculosis among cattle. Thus, contamination of children by the bovine type of tubercle bacillus, which results in a positive tuberculin reaction just as truly as

the human type, has practically disappeared. The number of beds in the county sanatorium has been increased to approximately 700. While there were 500 beds in this institution in 1926, an additional 200 has been added; this additional 200 is more beds for the tuberculous than exist in some whole states. The United States Veterans' Bureau has developed a hospital for 176 beds for the tuberculous. However, this institution admits patients from other parts of this state and from other states. Most of the general hospitals have opened their doors to tuberculous patients so that physicians can isolate and treat their private patients. In addition to the facilities for isolation, ambulatory artificial pneumothorax has definitely increased in popularity on the basis of results obtained, and many persons have had their lesions treated in this manner before they became spreaders of tubercle bacilli, while many others with tubercle bacilli in the sputum have had their lesions quickly controlled and the sputum rendered negative. Thus a vigorous effort has been put forth to isolate patients with tuberculosis in sanatoriums and hospitals and to treat them in the homes so as to prevent them from spreading bacilli to their human associates.

The most outstanding work is the epidemiology that has been practiced over this period of years. As soon as a case of clinical tuberculosis is reported, an earnest attempt is made, first, to find the source of the disease; that is, to find the person with tuberculosis who spread tubercle bacilli to the present patient. In fact, 26 per cent of the cases of clinical tuberculosis reported to the health department in 1932 were detected in this manner.² An attempt is made secondly to examine adequately all the immediate contacts who may have been contaminated by the present patient. When such contacts are not found to have tuberculosis in clinical form they are kept under close observation and examined periodically. This is done by private physicians for those who are financially able; for all others adequate clinics have been provided. It is not at all infrequent to find that the chest of a contact reacting positively to the tuberculin test and entirely negative to x-ray films and physical examination subsequently shows small shadows which make their appearance on the x-ray film long before symptoms or abnormal physical signs are present and long before tubercle bacilli are being eliminated in the sputum. Thus, many lesions which without such observation would become extensive and spread tubercle bacilli are brought under control without ever causing the patient any illness or being a menace to the individual's associates.

Another phase of the epidemiologic work which has been extremely valuable consists of the use of the tuberculin test among children, many of whom had no known contact with open cases of tuberculosis. By finding

2. Myers, J. A.: The Epidemiology of Tuberculosis, *J. Outdoor Life* 31: 50, 1934.

the positive reactors and tracing back to the family and other close associates, many cases of open tuberculosis previously undiagnosed have been brought to light. In fact, in a special chest clinic at the Lymanhurst Health Center, provisions have been made whereby x-ray films and clinical examinations are made of the chest of indigent persons. Moreover, physicians who have patients who can pay them a small fee but cannot afford x-ray films of the chest are permitted to send such patients to this clinic for free x-ray work. Indeed, during the present year x-ray film examinations have been made of approximately 5,000 persons in this clinic.

In addition to this method of finding unsuspected cases, the school board passed an order in 1933 requiring all employees of the school system to be adequately examined for tuberculosis. Thirty-six hundred such employees were examined, sixty-eight of whom showed shadows on the x-ray film which required clinical examination and observation to determine whether they were cast by tuberculous lesions and if so whether they were in a progressive or communicable stage. At the time this work was reported,³ six employees were found to have tubercle bacilli in the sputum and, since, two others have become spreaders of tubercle bacilli. The remainder are still under observation. While this number of communicable cases of tuberculosis may seem small, it is not difficult to conceive of them spreading tubercle bacilli to large numbers of girls and boys in the school system, since it has been estimated that one patient with open tuberculosis may eliminate from thirty to forty million tubercle bacilli daily.

Moreover, a very fine educational program for physicians has been carried on during the past few years in which the department of health, the local medical society and the county tuberculosis association have cooperated. Tuberculin syringes were presented to each physician in the county and every two weeks tuberculin in a dilution of 1:1,000 is delivered free of charge to the office of each physician who desires to use it. Free tuberculin to physicians for testing is not a new idea. In 1893 a law was passed in Denmark which provided for the expenditure by the minister of the interior of \$13,500 annually for five years to provide free tuberculin for testing cattle.⁴ In our present program this has resulted in large numbers of tuberculin tests being administered by private physicians, whether engaged in special or general phases of medical practice, and many of the persons reacting positively to the test have had adequate subsequent examinations to determine whether tuberculosis is present in clinical form. This work by the private physicians has not only uncovered many previously unsuspected cases of tuberculosis but has also been of great educational value to the public, particularly with reference to the contagiousness of tuberculosis.

In Minneapolis, as in most cities, the work of controlling tuberculosis has of necessity been fragmentary. Not enough public health education has yet been possible to convince all persons of the value of periodic examinations for tuberculosis. Funds are not available to carry out an ideal program among the indigent, but it is obvious that, if the work which is already under way could be extended to every home and every individual and proper cooperation were afforded, all the

foci which are spreading tubercle bacilli could be quickly treated or isolated. The potential communicable cases could be kept under very close observation and in a relatively short time there would be no spreaders of tubercle bacilli.

Even though an ideal program has not been possible, we were convinced that much had been done to prevent the spread of tubercle bacilli and that the tuberculosis problem had been definitely decreased. To measure the effectiveness of the program in the past, we had at our command a method that would give us very definite information; namely, the tuberculin test.

Soon after Koch⁵ presented tuberculin in 1890 it was learned that the dose recommended by him both for diagnostic and for therapeutic work often resulted in severe and harmful reactions. He used the subcutaneous method of administration. However, when Pirquet⁶ and Mantoux⁷ perfected the epidermal and intradermal tests, the amount of tuberculin used by them was found to be without harm. They were convinced that tuberculin is specific as a diagnostic test and through its use made a revelation that could not have been made in any other manner. While it was true that pathologists had already observed tuberculous lesions in large numbers of persons who had died of other causes, the tuberculin test revealed the fact that a high percentage of apparently healthy girls and boys had been infected with tubercle bacilli by the age of 15 years. We often think of Pirquet and Mantoux as believing that tuberculous infection was almost universal in young adults throughout the world, but this is far from true. Indeed, regarding his own observations, Pirquet⁸ said:

This high percentage cannot be considered as being the figure for all children, as very many cases are admitted into the hospitals because of tuberculosis.

Again he said:

The percentage of infected (reacting) children is a particularly high one in my table. In other cities it will hardly be as high because tuberculosis is notoriously prevalent in Vienna. Furthermore, all my patients belonged to the poorer classes. My statistics, therefore, lose in some degree their general value. Our children are infected at a much earlier age on account of the prevalence of tuberculosis among their parents. It is necessary to make similar studies in every city in order to ascertain the frequency of tuberculosis in general.

Thus Pirquet recommended the tuberculin test as the method of determining the incidence of contamination with tubercle bacilli in various parts of the world. Since the time of Pirquet and Mantoux the tuberculin test has been used very extensively, and at present it is recognized as a test having no superior in the diagnosis of any disease. Careful experimental studies and close observation on human beings have revealed the fact that when tubercle bacilli grow in the human body during the early stage of tubercle formation their protein sensitizes the tissues of the body. While microscopic evidence of sensitiveness of tuberculo-protein can be detected a short time after tubercle bacilli are introduced into the animal body,⁹ it is usually a period of approximately two or more weeks before the tissues are so sensitized as to react positively when tuberculo-protein is brought in contact with the skin through an

abrasion or is introduced hypodermically within the layers of the skin. In the human body, where the time of exposure is quite accurately determined, it requires from three to seven weeks¹⁰ for the tissues to become so sensitized as to give such a reaction.

There is nothing ordinarily taken into the human or animal body which causes sensitization of the tissues to tuberculo-protein except tubercle bacilli themselves which are resulting in or have resulted in tubercle formation.¹¹ It is possible to produce such sensitization artificially in the laboratory by the use of dead tubercle bacilli or the protein content of tubercle bacilli. However, this is usually of short duration because it is eliminated and not further produced, whereas that which develops through tubercle formation in the human body is usually thought to be of long duration because of continuous production from living bacilli. Since tubercle bacilli in tubercles and the lymph nodes of the primary complex often remain alive over long periods of time, they actually constitute manufacturing plants of tuberculo-protein in such quantities as to keep up the sensitization. Evidence has accrued to show that in some persons who are apparently well and who have previously reacted positively to the tuberculin test the sensitiveness of the tissues becomes so decreased that it is impossible to produce a reaction even with large doses of tuberculin. How frequently this occurs is not known. It is a possibility that the tubercle bacilli which result in the tubercles of first infection may be destroyed, after which there is no longer a source of tuberculo-protein in the body and the tissues completely lose their sensitiveness. It has long been known that in overwhelming acute tuberculous processes, such as pneumonia, meningitis and miliary disease, the tissues are often desensitized so that it is impossible to obtain a positive reaction from the tuberculin test except when large test doses are used. Again, in chronic forms of tuberculosis during the terminal stage there may be enough tuberculo-protein produced and liberated to desensitize the tissues. Occasionally one sees a person with chronic tuberculosis who is by no means in the terminal stage and yet the tissues fail to react to the tuberculin test. Apparently the number of such persons is small, and no one has made sufficiently long observations to determine whether in the same individuals there was at an earlier time definite sensitization of the tissues. It is probable that such cases may have become desensitized through the tuberculo-protein produced in their own bodies. These changes in human beings are not essentially different from those which the veterinarians observed in the nineties. Indeed, Bang⁴ of Denmark, in writing of the disadvantages of tuberculin in the testing of cattle said:

In the first place the violence of reaction has no constant relation to the development of the disease. Farmers often believe the cow reacting violently to be extremely tuberculous and the one reacting feebly to be comparatively sound. The case is rather the reverse, but this is not constant either. Next, tuberculin is not absolutely to be relied upon. To be sure you will very seldom be mistaken in the conclusion that a cow which has shown an evident reaction is indeed tuberculous. I, for my part, know only three or four cases in which I could find no tuberculous deposits in such an animal, and in these cases the fault may be mine and not that of tuberculin, as it is impossible to examine every part of the body of a slaughtered animal. The tubercles may have been hidden in an unusual place, or

they may have been so small or so fresh that they could not be discovered. This case then is a very rare one, though the unskilled observer, for instance, the butcher, may believe it to be a frequent one. Moreover, it must be considered that it would not be a disaster even if a sound animal should for once be considered tuberculous. Far more frequent is the case that an animal which has not reacted is proved by slaughtering to suffer from tuberculosis. But usually this has not the practical importance one would suppose it to have, as in the great majority of cases the deposits in question are very small, very old or greatly calcified, indicating that the process has become stationary. Experience teaches that such small deposits usually keep quite unchanged for a series of years and may even at length be healed. In fact, animals which have this form of tuberculosis will be quite harmless to their associates as they do not excrete tubercle bacilli. But there are also cases in which an animal suffering from far advanced and very contagious tuberculosis does not react to tuberculin. This is a very provoking fact; luckily, however, it happens but seldom, and we must be taught by it not to rely on tuberculin alone but to have recourse to clinical examination which will usually enable us to detect tuberculosis in such advanced forms. In the third case, tuberculin has the imperfection that reiterated reactions will not rarely call forth a temporary insusceptibility to the substance so that tuberculous animals will at length cease reacting to a new injection. This circumstance may occasion fraud in dealing in cattle, but as the fact is very inconstant the imposture will by no means always be successful. . . . But the imperfections of tuberculin mentioned here are eclipsed by its good qualities. According to my experience, which is founded on a very great number of autopsies, it is in 10 per cent of the cases at most that tuberculin will be at fault and it is only in a very small percentage of these cases that the fault will be of consequence. Tuberculin, therefore, in spite of its imperfections, marks an immense advance in the diagnosis of tuberculosis. By its help we are able to discover a great number of cases of tuberculosis which were formerly absolutely concealed. Until something still better has been found, we must consider it to be our best weapon in the struggle against tuberculosis of cattle.

Thus those who believe that the finding of the occasional person with tuberculosis who does not react positively to tuberculin is a new discovery may be surprised to learn that this fact was known to the veterinarians forty years ago. Moreover, one may look on the occasional failure on the part of tuberculin as insignificant in a control program just as the veterinarian does.

The tuberculin test is extremely valuable in determining who in a family or in a community has foci of tubercle bacilli in the body. A positive reaction is diagnostic of the first infection type (primary complex) somewhere in the body. This type rarely causes significant illness but is always the forerunner of reinfection destructive forms of disease, both acute and chronic, when this type develops. The tuberculin test, therefore, serves as a screen to select those who have been infected through direct or indirect exposure and who should be carefully examined and kept under close observation thereafter for the development of clinical disease.

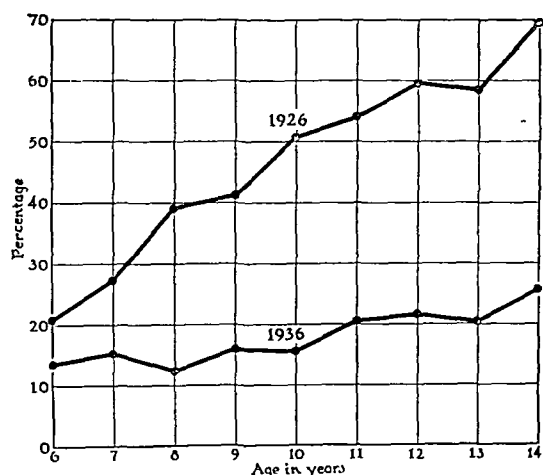

During the months of April and May 1936, we tested 4,549 children in the schools in which testing had been done ten years ago. There has been a sharp decrease in the percentage of children reacting positively to the test, as shown in the accompanying chart, indicating that the environment of the present school children has been very much better so far as exposure to tubercle bacilli is concerned than was that of the children in the same age period ten years ago, when 47.33 per cent reacted positively. In the accompanying table the positive reactors have been grouped according to age. To expect another sharp decrease in the next ten years would not be illusory, provided the present program of preventing contact of children with open cases of tuberculosis can be continued and extended.

11. Krause, A. K.: Human Resistance to Tuberculosis at Various Ages of Life: Appendix A. Remarks on Conditions Necessary to Arouse the Allergic State and on Immunity Through Fixation of Bacteria. *Am. Rev. Tuberc.* 11: 303 (June) 1925.

In many parts of the country, the number of positive reactors among children and young adults is decreasing. In these places, programs similar to that employed in Minneapolis have been in effect so as to reduce definitely the number of communicable cases of tuberculosis through isolation, treatment and other measures, thus creating an environment for children with far fewer tubercle bacilli than that of former years. For example, in Detroit ¹² in 1930, of 5,044 children examined, 54 per cent reacted positively while in 1935, of 5,504 children examined, 26 per cent reacted positively. While the rate of decrease in positive reactors apparently has been rapid, it should be accelerated, as the number of communicable cases of tuberculosis in any community is decreased through serious effort to locate and render their disease noncommunicable or to isolate them. Obviously, the lower the incidence of tuberculous infection in any community, the more valuable the tuberculin test; likewise, the problem of examining and keeping under close observation all the positive reactors becomes a physical possibility.

The tuberculin test is easily administered and the cost is small, but other phases of the examination, such as

Percentages of the children acting positively to the test in 1926 and 1936.

making of x-ray films, are more expensive. Therefore, with relatively small expense and in a short time through the tuberculin test, one can select those who need further examination. For example, if in a given community 15 per cent of the children and young adults react positively to the tuberculin test, one immediately eliminates the 85 per cent who at that time do not need any further examination for tuberculosis.

Some workers have found more positive reactions with old tuberculin, while others have reported more with purified protein derivative. The recent work of Plunkett ¹³ showed that when the larger doses of the two preparations are employed simultaneously at different sites on the same individuals there is essentially no difference in the percentage of positive reactors. The potency of old tuberculin from various drug houses varies considerably. This is a rather serious objection. The chief advantage of purified protein derivative is that it is standardized, so that its potency is the same wherever it is used. This, of course, insures more uniform results than when old tuberculin is used. The only objection to purified protein derivative is its high cost. In our present study we employed old tuberculin

secured from the Saranac Laboratories, since this tuberculin had been used in our study of a decade ago.

The present method of administering the tuberculin test in two doses is objected to by many workers, since all who do not react to 0.01 mg. of old tuberculin or the first dose of purified protein derivative should have a second dose consisting of a full milligram. For example, if tests are to be made on 100,000 children in a community where only 10 per cent react positively to the first dose, 90,000 must be retested. In short, the expense and time of testing is nearly doubled. In our survey we employed an initial dose of 0.1 mg. and retested all the negative reactors with 1 mg. While each of us was able to administer from 300 to 500 tests in an hour, still much time could have been saved if a single test dose had been used. Many workers use 0.1 mg. of old tuberculin as the first and final dose; a few use a full milligram as the only test dose. Long ¹⁴ and his co-workers are about to present a single test dose of purified protein derivative, which should greatly facilitate tuberculin testing in this country.

Some physicians prefer other methods of administration than the intracutaneous, and also some persons object to the use of a hypodermic needle. For example, Chadwick, Pope and their co-workers use the epidermal method of Pirquet with excellent results. Slater, ¹⁵ by carefully administering tuberculin by the epidermal method on one arm and by the intracutaneous method of Mantoux on the other arm, finds a difference in positive reactions of only 1 per cent in favor of the intracutaneous method. However, in the hands of less experienced workers a larger discrepancy is usually reported. For those who even object to the scarification of the skin necessary for the epidermal test, a modification of the percutaneous test described by Lovett ¹⁶ and the tape test by Wolff ¹⁷ are valuable. Indeed these tests, when carefully administered, closely approximate in accuracy the intracutaneous test. However, their administration is slightly more time consuming.

The specificity of the tuberculin test has been demonstrated on such a large scale in animals that it can no longer be questioned. When Pearson and Cotton began using the tuberculin test to detect tuberculosis in cattle in 1891, they were convinced of its specificity. Although for the next two or three decades much opposition was voiced, those who were convinced of its specificity brought forth irrefutable evidence. For example, in some places 92 per cent of the cattle reacting positively to the test were found at postmortem examination to have macroscopic tuberculous lesions. In political divisions where tuberculin testing of the cattle herds was repeated periodically, the time arrived when less than 50 per cent of those reacting positively showed macroscopic lesions at postmortem examination. Another great controversy was initiated by the opponents of the tuberculin test on the ground that more than 50 per cent of the animals slaughtered did not show lesions and therefore did not have tuberculosis, whereupon the proponents called attention to the fact that tuberculous lesions begin their development in a microscopic way and that the test is so delicate that even such lesions are detected by it. They were simply catching up with tuberculosis; that is, they were diagnosing it before it could be seen with the naked eye. It was then their

aim to reach the time when all tuberculosis among cattle would be diagnosed while the lesions were still microscopic and long before those animals with such lesions could spread their bacilli to others. They have now reached the ultimate goal; namely, complete eradication of tuberculosis from large numbers of herds and from all the herds in a few entire counties. All that remains is to use the same method that has led to this goal in the remaining parts of the country and tuberculosis will be completely eradicated from our animal herds. Indeed, by the close of the year 1937 all states will be accredited, with the possible exceptions of South Dakota and California. This is the greatest revelation of all time with regard to tuberculosis control, and it is one of the revelations of the tuberculin test. Without this specific test it would not have been possible to eradicate tuberculosis from the animal herds.

this disease passes through many phases and stages from the time the neutrophil phagocytoses the first tubercle bacillus until the disease takes the life of the individual. Unfortunately, it was not considered that a person had tuberculosis until he was ill, when in reality the disease had existed since the tubercle bacilli were first focalized by the neutrophils. About two years ago a committee of the Minnesota Trudeau Medical Society strongly recommended that all persons who react positively to tuberculin be reported to the health department. The society rejected the report and similar action has been taken against such committee reports in other states. However, in Minneapolis the commissioner of health strongly encourages physicians to report all positive tuberculin reactors even though the disease cannot be located by present methods of examination. Such reports are of great help to the health

Positive Reactors Grouped According to Age

Age	Sex	Number Tested	Positive 1:1,000	Negative 1:1,000 Positive 1:100	Positive 1:1,000 or 1:100	Total Number of Complete Tests	Total Number Positive
5.....	Male	31	4 (12.9)	1 (3.2)	5 (16.1)	63	11 (17.5)

The tuberculin test is no less specific for human beings than it is for cattle. Indeed, the veterinarian uses tuberculin made from the human type of tubercle bacilli for testing cattle just as we do for testing human beings.

Through the tuberculin test and slaughter of the positive reactors, the veterinarian quickly recognized a long latent stage in tuberculosis but did not complicate the situation by calling it infection rather than disease. The following quotation from the report of a committee headed by Dr. John R. Mohler¹⁸ is significant: "When the tuberculin test is applied to cattle for any purpose it should be clearly understood that the reacting animals are to be regarded in every sense of the word as recognized cases of tuberculosis, which under an obligatory notification law must be reported at once to the proper authority." In human medicine, one must recognize the fact that a positive tuberculin reaction indicates the presence of tuberculosis somewhere in the body. For too long the fact has been overlooked that

officer, who is often able to assist the private physician in finding sources of exposure. A list of positive tuberculin reactors is also valuable because they are potential cases of clinical tuberculosis and should be examined periodically.

Although the reporting of persons who do not show any evidence of tuberculosis except the positive tuberculin reaction is strongly opposed at the present time, it must eventually be considered as an important part of a tuberculosis control program. Here again we are only recommending what the veterinarian has found so effective in eradicating tuberculosis from the cattle herds.

Through the tuberculin test and slaughter of the positive reactors, the veterinarian learned that, once tubercle bacilli gain lodgment in the animal's body, an actual or potentially serious condition exists. Of this Pearson and Ravenel⁴ say:

It is a disease that runs a chronic course with but little tendency to heal, although it is sometimes latent for a long period. Even if the animal recovers, it is not thereby rendered immune to another attack as is the case with hog cholera, anthrax, influenza and numerous other diseases. Therefore,

18. Mohler, J. R.: Report of Committee on Location of Tuberculosis in Cattle, Appendix. Moore, Veranus: Bovine Tuberculosis and Its Control, Ithaca, N. Y., Carpenter & Co., 1913, p. 121.

when tuberculosis is introduced into a herd it is not self limiting and its tendency is constantly to spread and with a degree of rapidity that depends largely upon the sanitary conditions to which the herd is subjected.

Again they say:

After gaining a foothold in the body and after one or more tubercles are formed, the bacteria may invade other regions by passing through tissue, by being distributed mechanically in cavities or in canals or by being transported in currents of lymph or in the blood.

Moore¹⁸ says:

It is not known how long the lesions may lie dormant, but we have individuals where they sprang into activity after three and one-half years, and also a case where an apparently healed, calcified tubercle contained living virulent tubercle bacteria three years after the cow ceased to react.

In the human body one can no longer look lightly on the primary tuberculosis complex when its presence is indicated by the positive tuberculin reaction.

The next step in our present survey consisted of making x-ray films of the chests of the children who reacted positively to the tuberculin test. Although the fact is well established that the positive tuberculin reaction establishes the presence of a primary complex somewhere in the body, the lesions that constitute this complex usually are not of clinical significance except in a few cases for a brief period of time as allergy appears, when there may be an elevation of temperature. Subsequent to this period there are no clinical manifestations. The x-ray film of the chest fails to reveal the location of the primary complex in 75 per cent or more. Moreover, knowing the location of the complex is of no material assistance to the clinician.

We no longer recommend making x-ray films of the chests of children except for the detection of developing reinfection or the clinical type of tuberculous lesions. Since this type of lesion is found in the chests of children who are positive tuberculin reactors only once in 2,000 or 3,000 examinations, it is hardly worth while to make x-ray films of the chests of children, since there are other age periods in life when films reveal so much more evidence of clinical tuberculosis. For example, during the high school age period one may expect to find evidence of developing clinical disease in one in every 500 to 800 positive reactors. In the college age period a larger number of positive reactors is found to have developing or well established clinical disease, whereas in the twenties and thirties one may find a case of clinical tuberculosis in every 100 or 200 positive reactors.

The form of tuberculosis that causes illness, requires treatment and disseminates tubercle bacilli to other human beings is largely a disease of adult life. Our chief reason for making x-ray films of the chests of the positive reactors in this study was to obtain confirmatory evidence concerning the absence of clinical disease in the chests of children which we have previously observed in other groups.

Considerable controversy has arisen regarding the necessity for treating children who react positively to the tuberculin test whether or not the primary complex is located by further phases of the examination. However, sufficient evidence is now available to justify the statement that active treatment is not necessary for such children. They do just as well in their homes as they do in institutions, and they do just as well in school and other usual activities as they do lying in bed at home.¹⁹

While children with the first infection type of tuberculosis in the inflammatory stage may occasionally have tubercle bacilli revealed in the gastric contents, they rarely cough or expectorate; therefore they are not public health menaces. Active treatment was not recommended for a single child found in this study to react positively to tuberculin, because our observation with all forms of treatment on similar groups of children over a period of fifteen years has conclusively proved that treatment is of no avail.

This does not mean that our survey was of no value, for finding the positive reactors gave us two very definite leads that are of great importance in the tuberculosis control program: First, we learned from each positive reaction that the child had been exposed to a communicable case of tuberculosis. While it is true that a visit to a neighbor or a distant relative may suffice to set up a focus of tuberculosis in the child's body, it is also true that some positive reactors are in close association with persons who have communicable tuberculosis which may never have been diagnosed. Therefore, one of the prime objects of this survey was to seek the source responsible for the disease in each of these children and to stop any further exposure by isolating or treating these persons. This is being done as fast as possible.

Second, close observation is important for every child who reacts positively to the tuberculin test as soon as young adult life is reached, since the fact has been well established that in a good many such children clinical disease develops during adult life. Indeed, in a group of children (average age about 8 years) reacting positively to the tuberculin test in 1921-1922, we have found that approximately 10 per cent have already developed clinical tuberculosis.²⁰ In other groups reacting positively in each succeeding year, corresponding percentages have developed a manifest reinfection type of lesion.

Therefore, all these children who have reached the period of adolescence and all others as soon as they approach this period should have annual x-ray examinations of their chests. In this age period and thereafter the x-ray film is indispensable in the tuberculosis control program. When reinfection or clinical pulmonary tuberculosis is found to be developing, treatment should be instituted at once, for this is the form of disease that causes most of the serious illness and death from tuberculosis. By such a program of observation, practically all children who develop clinical disease will have it detected before symptoms are present and before it has become communicable. This is the time when tuberculosis can be treated most successfully in a very short time, and usually treatment will prevent the individual from falling ill or from becoming a disseminator of tubercle bacilli. Here collapse therapy, particularly artificial pneumothorax, is the most effective form of treatment and often can be instituted and maintained on an ambulatory basis.²¹ When such a program of breaking contact is carried to its logical conclusion, tuberculosis must rapidly disappear.

In the whole educational campaign against tuberculosis in recent years, nothing has been so valuable or so significant as bringing to the attention of the public the fact that this disease is contagious. Indeed, it was

the veterinarians' early recognition of this fact that added much to the success of their work. Moore¹⁸ says: "Tuberculosis has gradually grown into many herds of dairy cattle. It should be guided in such a way that it will grow out. The secret of accomplishing this is to prevent the spread of tubercle bacteria from the present infected cattle so that with the disappearance of the animals now infected this destructive disease will be no more." In our epidemiologic work we are practicing the veterinarian's method of finding cases of tuberculosis and breaking contact with others.

The Bang method of control provided that all calves from cows reacting positively to the tuberculin test should be removed immediately after birth and fed on milk that had been heated or milk from cows that did not react positively to the test. When these calves reached the age of about 4 months they were tested again and periodically thereafter. Throughout the remainder of their lives they were kept away from other animals reacting positively to the tuberculin test. This is essentially the same procedure that Grancher, Bernard, Hess and many others in more recent times have employed for infants. Where this procedure has been practiced even in a very incomplete manner there has been a sharp reduction in mortality, morbidity and the development of primary complexes from tuberculosis. In fact, Boynton²² has pointed out that in the state of Minnesota the mortality from tuberculosis in infants decreased 88 per cent from 1916 to 1933.

We know all that is necessary in order to control tuberculosis in the human family, and the method now in use has been proved to be sound. If this method is employed everywhere no immunizing agent will be needed. In fact, to the present time no satisfactory immunizing agent has been developed. The veterinarians have made numerous attempts to immunize cattle against tuberculosis. As early as 1913, Moore¹⁸ said:

It is impossible in a work of this kind to enter into a discussion of the theories of immunity, but the fact that individuals who have suffered an attack of tuberculosis and have recovered at least temporarily are not protected against a subsequent attack or recurrence does not argue in favor of a protective vaccination. Success may be attained but at present there seems to be no method that can be recommended to the cattle owner for successfully vaccinating or immunizing his animals against tuberculosis.

Since Moore's statement, other attempts have been made, including such preparations as Calmette's vaccine, BCG. After sufficient trial, however, the veterinarians of America have not adopted BCG as a satisfactory method of prevention. They have had a better opportunity to observe the effects of BCG on cattle than we could ever hope to have on human beings. The veterinarian's experience and his record of success in controlling tuberculosis, which is the best of any group of workers of any time, should discourage every physician from administering BCG to children. Certainly a preparation that the veterinarian considers unsafe and ineffective for cattle should not be used in an experimental way on the children of the United States. To prove the efficaciousness of an immunizing agent for tuberculosis in the human body would require decades; in fact, before this can be proved, our present method should reduce the disease in the human family to one of minor importance.

NONDRAINAGE OF THE PERITONEAL CAVITY IN APPENDICEAL PERITONITIS

EDWARD A. CAFRITZ, M.D.

WASHINGTON, D. C.

Since Mikulicz¹ expressed the opinion that a gangrenous appendix may be removed and the peritoneal cavity closed without the introduction of a drain, attempts have been made by various surgeons throughout the world to use this method in certain cases. Although since then the subject of drainage or non-drainage of the peritoneal cavity in the presence of peritonitis has been extensively studied, there seems to be no uniform opinion regarding it. Some state that it is best to drain the infected abdominal cavity, while others believe that drainage prolongs hospitalization, promotes the development of ileus, favors the development of ventral hernia and of intestinal adhesions and is in general contraindicated.

Even the proponents of nondrainage are somewhat hazy with respect to indications and contraindications.

With the introduction of asepsis and the consequent popularization of surgical treatment in general, there gradually developed the idea that in the presence of peritonitis, now known to be most frequently the result of an extension of the inflammation to the peritoneum from the acutely inflamed appendix, best results could be obtained by removal of the focus of infection, be it a ruptured appendix, a ruptured cyst or a perforated bowel, and a consequent introduction of a drain, consisting of a rubber tube, sterile gauze, a Penrose drain and the like. The idea of drainage is based on the prevalent but erroneous belief that the absorption power of the peritoneum is, in comparison with other serous membranes, very great, and the mechanical release, through the drain, of the infectious substances is bound to speed up recovery and to facilitate healing. This, in brief, is the rationale of "draining."

Numerous objections can be given to refute this theory. Not going into an extensive discussion of the anatomy and physiology of the peritoneum, I may briefly state that the absorption of the peritoneum is not greater than that of any other serous membrane, that it occurs chiefly along the region lining the diaphragm, and that one must bear in mind that it is physically impossible to drain the entire peritoneal cavity by means of the usual type of drain employed for this purpose.

Poynter,² who made a thorough study of the problem of peritoneal absorption, came to the conclusion that drainage for peritonitis is illogical in that absorption has contaminated the general circulation long before any operative procedure can be instituted and that the process can be little, if at all, influenced by so-called surgical drainage.

It is a physical impossibility to drain the entire peritoneal cavity even by multiple incisions and drains. It can be proved experimentally that from twenty-four to forty-eight hours after the drain is introduced the intestinal loops or omentum are widely agglutinated around the drain and that the actual area of drainage corresponds roughly to that of the surface area of the drain itself.

22. Boynton, Ruth E.: The Declining Death Rate from Tuberculosis in Children: An Analysis of Tuberculosis Deaths in Minnesota from 1915 to 1932. *J. A. M. A.* 104: 1875 (May 25) 1935.

1. Mikulicz, J.: *Samml. Klin. Vortr.*, 1885, No. 262.

2. Poynter, C. W. M.: *Nebraska M. J.* 14: 362 (Sept.) 1929.

Miller,³ who made a thorough study of the subject and also reviewed the literature, came to the conclusion that drainage increases postoperative discomfort, prolongs convalescence and is in many cases the cause of secondary operations.

Stanley Raw advocates closing the abdomen in all cases in which the appendix has been removed. He has employed this method since 1921 and finds that there is less suppuration without drainage than with it.

Banks favors nondrainage in all cases of spreading and diffuse peritonitis whenever it is possible to remove the cause.

Marchini⁴ reported 301 cases of localized peritonitis; drainage was used in 184, with nine deaths; drainage was omitted in 117, with two deaths; there were 142 cases of diffuse peritonitis; drainage was used in 101, with thirty-one deaths; drainage was omitted in forty-one, with seven deaths. These figures show, therefore, that of the 158 patients with localized or diffuse peritonitis, without drainage, nine died, giving a mortality slightly less than 6 per cent, while of the 285 patients with drainage, forty died, giving a mortality of a little over 14 per cent.

Shipley⁵ and Bailey, who recently made a study of the subject of treatment of appendicitis with peritonitis, came to the following conclusions:

1. Exclusive of strangulated hernia, peritonitis is the chief cause of intestinal obstruction.

2. In the majority of instances it is not the peritonitis *per se* that causes the adhesions and bands leading to obstruction, but the reaction of the peritoneum to the drain.

3. Drainage material, especially in the lower abdomen, often causes widespread adhesions between loops of intestine, mesentery, omentum, pelvic organs and abdominal wall.

4. Drains are soon sealed off and do not drain any considerable portion of the peritoneum.

5. Paralytic ileus seriously obscures the clinical picture when drains are left in the abdomen.

6. Pelvic drains increase the incidence of postoperative retention of urine.

7. Drained abdomens are most likely to develop troublesome, painful, or disabling late postoperative adhesions.

8. Late intestinal obstruction is more likely to occur in drained than in undrained abdomens.

9. None of these considerations should carry weight if the risk of life is increased by closure without drainage.

10. Evidence is accumulated that the introduction of drains into the abdomen in the treatment of early peritonitis may be dispensed with, without increase in the death rate.

In order to ascertain the opinion of the leading American surgeons regarding the question of drainage or nondrainage of the peritoneal cavity in appendiceal peritonitis, a number of questionnaires of the following type were sent to the leading surgeons and surgical clinics of America:

1. Do you use drainage of the peritoneal cavity in operative cases of appendiceal peritonitis as a routine measure?

2. If "yes," do you concede exceptions from this routine, and in which cases?

3. If "no," in which cases do you use drainage?

4. What do you consider the advantages of drainage, and what do you consider the disadvantages?

5. What do you consider as the advantages of nondrainage, and what are the disadvantages?

6. Remarks.

A study of the replies shows that the first question, "Do you use drainage of the peritoneal cavity in opera-

tive cases of appendiceal peritonitis as a routine measure," brought twenty-five clear-cut negative answers, seven definitely positive replies, and seven answers with reservations; i. e., the problem was discussed in general and reasons were given for "drainage" or "nondrainage" in certain cases. These replies are unusually significant in that they represent a cross section of the opinion of the leading surgeons of the country. We are dealing here, therefore, not with theoretical considerations but with actual realities. In each case the use of drainage or nondrainage is based on actual clinical results which dictate one or the other method of procedure.

As further seen from the replies to the questionnaire, the grounds given by the majority of surgeons for nondrainage are essentially as follows:

1. It is doubted whether drainage of the peritoneal cavity as a whole can actually be obtained, since any drainage is walled off within a few hours.

2. The drain acts as a foreign body, increases pain, prolongs convalescence, favors the development of postoperative ventral hernia and increases the incidence of postoperative intestinal obstruction, or mechanical ileus, by increasing the tendency to the development of bands and adhesions.

3. Nondrainage shortens convalescence, eliminates the possible reaction to a foreign body, decreases the tendency to postoperative intestinal obstruction or mechanical ileus, permits the peritoneum to attain a state of normality in a relatively shorter period of time, gives a better scar, since the wound heals as a rule by primary intention, and eliminates the possibility of fistula formation.

The grounds cited in favor of drainage are largely the following:

1. It removes tension and permits an avenue of escape for the pus and necrotic tissue that may be present. The removal of these substances is advantageous because it is known that they serve as excellent culture mediums for the pathogenic organism responsible for the infection, and indirectly maintain the infection.

2. It prevents a generalization of the process in cases of a walled-off abscess and minimizes absorption of infected material.

3. The walled-off pocket may be reached through the wound without its being reopened.

4. It decompresses abscess cavities and permits healing from the bottom.

5. It exteriorizes or walls off a damaged area from the general peritoneal cavity.

6. It is a necessity for taking care of leakage from a hollow viscus and to provide an exit for pus produced by tissue which has none of the specific qualities for limiting and combating an infection.

7. It maintains the patency of the opening in the abdominal wall during the time the processes of healing are obliterating the abscess cavity; it likewise establishes a tract along which a fecal fistula may drain in case the wall of the cecum is infected and in case of inadequate closure of the appendiceal stump.

Some of the answers indicate that in many instances drainage is used too often, that one still follows the dictum "when in doubt, drain." It cannot be denied that in some instances the logical method of procedure is to drain. I have reference to the cases in which, because for some reason the focus of infection cannot be removed, when one deals with a walled-off abscess or when necrotic or suppurative tissue is left in the abdo-

4. Marchini, F.: *Arch. ital. di. chir.* 28: 549, 1931.

5. Shipley, A. M.: *South. Surgeon* 3: 303 (Dec.) 1934.

men. Illogical, however, is the "routine" drainage of the peritoneal cavity in every case of appendiceal peritonitis. Management of this type is unquestionably responsible for many unnecessary deaths due to appendiceal peritonitis. Many surgeons have correctly stated in their answers that "blanket rules cannot be given and that the judgment of the surgeon in each case must determine the indications or contraindications to drainage."

Trinca,⁶ in his recent communication based on an analysis of 244 cases of diffuse peritonitis treated without drainage, comes to the following conclusions:

1. Owing to the nature and distribution of the contents of the peritoneal cavity, it is physically impossible to effect adequate drainage in cases of diffuse peritonitis.

2. Attempted drainage is not necessary when the primary focus has been adequately dealt with.

3. In the majority of cases it is unnecessary to remove the peritoneal exudate in the operative treatment of peritonitis.

4. The low mortality obtained in a series of 244 cases of diffuse peritonitis indicates that peritonitis in the early stages is not a serious condition if treated on rational lines.

5. The drainage tube should be abolished whenever possible in the operative treatment of peritonitis.

One must remember that the peritoneum is, as a rule, capable of coping adequately and successfully with an infection. This can be facilitated by the surgeon when the original focus of infection is removed, whether it is a ruptured viscus or a gangrenous appendix. If the general condition of the patient is satisfactory, this measure alone, plus adequate administration of fluids in the form of saline solution, dextrose, blood, and cardiac stimulants, if necessary, would eventually permit an uneventful recovery.

In cases in which the infection is produced by one or more very virulent organisms, the drainage is of more than questionable value because the infection has spread throughout the body, through the lymph and circulatory systems, long before the surgical treatment has been instituted. If the infection is less severe, the introduced tube fails of its purpose of drainage, since the entire peritoneal cavity cannot be drained, and actually increases the danger to the patient by serving as a foreign body, predisposing to the formation of adhesions and consequently to mechanical ileus, and, even under the most favorable conditions, prolongs hospitalization, adds to the discomfort of the patient and interferes with the formation of a strong healthy scar.

CONCLUSIONS

In the course of the last few years I have treated about twenty-five cases of appendiceal peritonitis along the lines mentioned; namely, I have simply eliminated the focus of infection and closed the abdomen, introducing a rubber tissue drain down only to the closed peritoneum; the results obtained were so encouraging that I believe I am justified in drawing the following conclusions:

1. Drainage of appendiceal peritonitis is indicated:

(a) In cases in which the primary focus of infection cannot be removed.

(b) In cases in which a large amount of necrotic and contaminated tissue is left in the abdominal cavity.

(c) In cases of walled-off abscess.

2. In all other cases of appendiceal peritonitis, drainage is definitely contraindicated.

3. The advantages of nondrainage are:

(a) There is less morbidity and less mortality.

(b) It minimizes the possibility of postoperative mechanical ileus.

(c) It shortens the duration of illness.

(d) It minimizes the tendency of postoperative hernia.

(e) It excludes the possibility of development of a fistula.

(f) It minimizes the tendency of postoperative adhesions.

THE SKIN REACTIONS OF INFANTS AND CHILDREN TO SOAPS

LEON GOLDMAN, M.D.

CINCINNATI

Surprisingly little is known at the present time of the actual mechanism of the action of soap on the skin. It is obvious that accurate knowledge of such a commonly used material would be of great practical value. Increasing interest in contact dermatitis has brought forth many questions about the rôle of soaps in the development of this condition. There is a vast amount of misinformation available chiefly through the all too powerful medium of propaganda advertising.

Clinical analyses of soap reactions are being made at the present time, chiefly through dermatologists. This is done by means of the patch test, controlled carefully. In 1928 Hazen¹ found eight cases of allergic dermatitis due to soap in a series of 127 patients. In his detailed studies of the patch test in 1931 Stauffer² mentioned soaps and asserted that most of the eczematoid reactions to patch tests with soap solutions occurred in the eczema (contact dermatitis) patient. He did not believe that the alkali content of the soap caused the skin reactions. On the other hand, in his review of soaps, Mayer³ stated that soap hypersensitivity was really an alkali hypersensitivity. Osborne and his associates⁴ have studied the eczematizing properties of soaps in greater detail. They examined 115 patients and found also that many more reactions were evident in the patient with dermatitis. As with the interpretation of the reactions of so many commercial products today, they said "it is obvious that it is impossible to determine the exact eczematizing substances in any given soap unless a complete list of the ingredients used in its manufacture is available." They believed, however, that "the fatty acid formed on hydrolytic dissociation together with many miscellaneous ingredients of soaps, most of which are known eczematizing agents, seem to us the most likely etiologic factors in the production of eczema due to soaps." In a series of seventeen non-selected cases of contact dermatitis, I⁵ found that pure

coconut oil soaps had a greater frequency of reaction than other types of soap, including the soaps with a weaker concentration of coconut oil. In five of my cases, soap was a possible etiologic factor. I suggested that sometimes soap may account for a relapse in contact dermatitis when the supposed causative agent had been removed. In his list of materials that commonly induce cosmetic dermatitis, Balyeat⁶ mentioned alkali, mercuric iodide and saponated solution of cresol as being responsible for skin reaction from soap. He listed also those toilet soaps which he found irritating to the skin.

Recently Hansen⁷ has studied the question of soap reactions on the skin. He has determined the time

* Arbitrary classification of the degrees of the erythema-edema reaction.

interval for the return of the usual p_H in an area washed with various types of soap. The strong alkalinic soaps, of course, required the longest period. He obtained no positive patch tests in his series to 10 per cent sodium stearate, 10 per cent sodium palmitate and 10 per cent sodium oleate. No significant reactions were obtained with tenth normal sodium hydroxide. In 8 per cent of his cases of eczema (contact dermatitis) he obtained vesicular patch test reactions to *sapo kalinus* (linseed oil, potassium hydroxide and coconut oil). He believed there was no true hypersensitivity to soap, the soap test being a nonspecific reaction. The injurious action of soaps (keratin layer) can be reduced to a minimum, Hansen said, by using a "truly good soap." Bonnevie⁸ too, from a study of some 800 patients with contact dermatitis, concluded that hypersensitivity, in the broadest sense of the term, to soap is very rare, less than 0.3 per cent of cases. In most of the cases of positive soap reactions, the offending agent was some material incorporated in the soap, as benzaldehyde, terpenes, tar and sodium perborate. Sodium perborate (Persil soap) was the commonest eczematogenic agent. There is no doubt, then, that the patient with a contact dermatitis reacts more frequently to soap than the person with a normal skin. This, as I⁵ have pointed out, is a very important practical point. Moreover, soap itself does not produce this positive patch test reaction but chiefly the materials incorporated in it.

To study more closely the reactions of soap on normal skins, it was decided to do this in children. A study of 129 cases was made. The children were all white, with normal skins, and no history, either personal or familial, of any type of skin hypersensitivity or of hay fever or asthma. The children were studied through the courtesy of the obstetric and pediatric services of the Cincinnati General Hospital. The subjects were all

observed during their entire hospital stay. This work reported is a preliminary survey and includes observations of the skin reactions to the patch test and to swabbings with soap solutions.

It seems necessary to review the technic of the controlled patch test. Jordon, Walker and Osborne say that "patch tests properly performed and interpreted should be a great aid in the diagnosis of soap eczema." If work on soap is to be standardized, exact details must be followed in the performance of the patch test. Our present-day technic of this test is the result of years of observation by able investigators since the days of the great pioneer work of Jadassohn⁹ and Bloch.¹⁰ There is some definite disagreement of that important property of the patch test, the concentration of the solution. In his tables, Mayer¹⁰ mentions the use of small bits of moistened soap particles and insists that the control reactions must be known for each type of soap used. Blumenthal and Jaffe¹¹ gave as soap tests 5 per cent soap in hydrous wool fat or 2.5 per cent in 70 per cent alcohol. Osborne and his associates⁴ have used soap solutions in dilutions of 1:100 and 1:400. In my work with soap over the past three years I have employed small bits of soap, 10 per cent solutions and 5 per cent solutions. Apparently, then, if one knows the reaction of soaps on the normal skin, the same concentration of soap may be used for testing the hypersensitive skin. Though there is some disagreement as to the concentration of soap solutions used, there is no disagreement on the time period of observation, from twenty-four to forty-eight hours. If the patch test is to be used to study skin reactions, the material must be kept on at least twenty-four hours. This is very important, especially if one wishes to observe the milder changes produced by soaps. At various times we have tried shorter periods of contact but they were not at all satisfactory. In our study with the children, those children who pulled off their own patch tests before the necessary time interval usually showed no reactions. When the same soap tests are done repeatedly, more agreement is found when the materials remain in con-

TABLE 2.—Reactions to 5 per Cent Soap Solutions

tact with the skin for from twenty-four to forty-eight hours. The location of the patch test is also of importance if one wishes to control the milder reactions of soap. When the patch test is done on areas in which there is a considerable amount of pressure and friction, an erythema reaction is made more severe. For the true idiosyncrasy to soaps the vesicular patch test reaction may be obtained on the back. For our purposes of study, the soap solutions were done, as a rule, on the flexor surfaces of the arm and forearm. It is important that the soap solution be in intimate contact with the skin. The adhesive patch usually accomplishes this result. In the infant skin, especially the new-born

infant, the adhesive irritation was fairly severe and the following technic was adopted: The soap solutions were put on a small piece of white washed cotton cloth, covered with a very large cellophane disk, and this combination was then bandaged completely with an extensive bandage. In this way the soap solutions remained on the same area for the period of observation and there was no irritation of the adjacent skin. It is important to repeat these well known details of the technic of the patch test because any significant deviation from them will give rise to faulty conclusions.

The intensity of the reactions was read according to the method of Bloch.⁹ In addition, an attempt was made to grade the degree of the erythema reaction. Unless the details referred to are adhered to closely, the examination of the erythema reaction is entirely valueless. For practical purposes, of course, the more severe reactions are the most important, the 2-3 reaction and beyond that. In this connection one must distinguish between two types of reaction, the toxic reaction type and the eczematoid reaction type.¹² The patient with contact dermatitis gives the eczematoid reaction. With the soaps and especially with their actions on normal skins, one is concerned with milder degrees of the toxic reaction type, chiefly redness and edema.

To simulate more closely the action of soap on the skin, a series of swabbings was done on a selected area. This area, on the mesial aspect of the arm, was swabbed fairly vigorously with a large cotton applicator dipped in the soap solution. The material was allowed to dry and nothing was put over the skin.

The soaps used in these experiments were seven common toilet soaps, which were purchased in the open market. The study is separated into two groups: the first, infants and older children and the second, the new-born. Five children were tested simultaneously with small bits of soap chips and the 10 per cent soap solutions. The intensity of the reaction was approximately the same. In one of the cases the 10 per cent solution gave a slightly stronger reaction than the bits of soap. To determine the influence of the time factor in the performance of the patch tests, five cases were tested with patch tests left on from several minutes to ten hours. The skin showed no reaction in any of these cases and the skin remained negative for a week afterward. Twenty-nine cases were tested to 10 per cent soap solutions.

From table 1 it is seen that the severe reactions were uncommon in this group of 113 tests on twenty-nine patients. There is also little difference between the various soaps used with the exception of soap 4 (a toilet soap containing cresol). Moreover, two patients showed a papulovesicular reaction to this soap. This agrees with the observation of Balyeat.⁶

Table 2, with sixty-nine tests on a smaller group of children (ten), shows about the same grouping of reactions. These tests were not made on the same children as the 10 per cent solutions.

Histologic studies of the mild soap reactions (toxic) were done. These were made of the reddish brown discoloration that follows removal of the patch test after forty-eight hours. At this time the skin is edematous and reddish brown, and the surface is furrowed with parallel fine linear markings. After a few days, branny desquamation occurs. Microscopic studies of the forty-eight hour stage showed wide separation of the lamellae

and areas of fragmentation of the stratum corneum. The stratum granulosum was thin but otherwise not abnormal. No parakeratosis was noted. No other appreciable changes were seen in the epidermis until the basal layer. Here the cells showed vacuolization, distortion, pyknotic nuclei and loss of pigment. There were scattered areas of lymphocytic infiltrate in the upper layers of the derma, with no definite relationship to blood vessels. No appreciable edema of the papilla was made out. No apparent changes in the skin appendages were observed. Detailed microscopic studies, especially of the fat changes of the skin, are being done now. No microscopic studies were made of the vesicular reaction to the patch test, the true eczematoid reaction of hypersensitivity.

Soap swabbings were done in the older children group with 10 per cent soap solutions. Only two soaps were tested in four cases. No changes were observed in the skin after swabbing from two days to eight days.

Eighty-two new-born infants were observed. The patch test was done by means of the patch test bandage on the upper arm. The tests were left on for twenty-

5	8	3	0	1	1	0
6	18	6	0	0	0	0

four and forty-eight hours. Twenty-one cases were examined by the patch test method and sixty-one by the soap swabbings. These infants were observed daily for a period of one week. It is important to note that immediately after delivery the child was rubbed every day with an antiseptic oil. No other materials were used on the child's body. In a few cases the patch tests were done a few minutes after birth and in these infants the vernix was merely rubbed away and the patch test applied directly to the skin. After the patch test bandages were removed the test sites were included in the general rubbing of the body with the antiseptic oil. Four different soaps were studied by the patch test method on the twenty-one new-born infants. Only nine reactions were observed. The reaction consisted of a faint, reddish brown area, which in several days showed pin-point desquamation. This change occurred usually from twenty-four to forty-eight hours after the patch test was removed from the skin. Of four soaps studied, one, soap 5, gave most of the reactions.

There is only a slight difference in reactions of the soaps, 5 being perhaps slightly stronger. The difference, however, is not very significant. It is rather interesting to note how few definite reactions were observed in these forty-eight tests on twenty-one infants.

Soap swabbings were done on the remainder of the new-born group, sixty-one new-born infants. Separate swabs were used on each patient and the material was rubbed in rather vigorously over the mesial aspect of the entire arm. These areas had been oiled some three and one-half to four and one-half hours before the swabbing. The swabbings were repeated daily for seven days. No skin reactions of any sort were noted by this method. Four soaps also had been studied in this group (1, 4, 6 and 7). Icterus and the "milk rash" had no effect on the reactions to soap.

12. Miescher, G.: Zur Frage der Spezität der ekzematösen Hautreaktion, Arch. f. Dermat. u. Syph. 173: 119 (Oct. 18) 1935.

Apparently it was not the preliminary oil rub of the skin of the new-born that caused the difference in skin reactions between the new-born and the older children, because a group of older children were taken and the oil was rubbed on from three and a quarter to four hours before the patch tests were made; also immediately before the patch test and also simultaneously with the patch test. These various methods did not seem to reduce the intensity of the reaction to the patch test with soap. This series, however, included only eighteen older children. Moreover, as has already been noted, Blumenthal and Jaffe¹³ advised 5 per cent soap solution in hydrous wool fat. Additional studies are being made at the present time to determine this difference in reaction between new-born infants and the older children.

In eleven patients, four new-born and seven children, the alkali neutralization curves with phenolphthalein and bromthymol blue after the method of Burckhardt¹³ were done. The testing was done both on areas previously swabbed with soap and on normal skin. The results were so variable that no definite conclusions could be drawn from the few cases examined. It appears that many extrinsic factors seemed to influence the test. These tests are being repeated at the present time using the newer method of Burckhardt with a 1:2,000 sodium hydroxide and 1:2,000 phenolphthalein solution.

Following the observations of Burckhardt,¹⁴ it seems that the question of soaps relative to the production of contact dermatitis by other materials is indeed an important problem. He found that the skin could be sensitized to nickel by the single application of nickel sulfate on the skin previously damaged by alkali or a strong alkali soap (schmierseife). The mechanism is certainly not known. The following reasons have been suggested: changes in keratin which allow for the passage of antigens into the skin, the mechanical removal of the upper superficial layers of the skin, the partial disappearance of the protective fat layer from the skin, and the changes in the buffer action of the skin. Before these complex problems are studied, it seems more advisable to know the workings of soaps on normal skin.

CONCLUSIONS

It is generally agreed at present that patients with a contact dermatitis react more frequently to soap than patients with a normal skin. The eczematoid (vesicular) soap patch test is uncommon. Substances incorporated in soaps are supposed to be the more important eczematogenic agents.

A study was made of the skin reactions of seven common toilet soaps on 127 children, including eighty-two new-born. The methods included patch testing and soap solution swabbings. No changes were observed grossly after repeated soap swabbings. Exacting details of the patch test technic must be kept; otherwise the interpretation of the mild (toxic) patch test reaction is valueless. The new-born infants reacted much less frequently to the patch test than the older infants and children. The differences between the patch test reactions of the various soaps were not marked save for an increased intensity of reaction with a soap containing cresol.

PROTAMINE INSULIN VERSUS ORDINARY INSULIN

ANTHONY SINDONI JR., M.D.

Chief of Diseases of Metabolism, St. Agnes Hospital
PHILADELPHIA

Hagedorn and his co-workers¹ have prepared from the sperm of a trout (*Salmo iridius*) the substance protamine, which, properly buffered, combines with insulin to form the compound protamine insulinate or, for want of a less confusing name, "protamine insulin." When this compound, which is sparingly soluble in the tissue fluid, is given hypodermically, it slowly breaks down so that the active insulin is gradually released and absorbed, thereby causing a continuous and prolonged action on the blood sugar.

It has been reported that occasionally the final effectiveness of protamine is delayed beyond the day of its administration as late as four or five days.² The duration of this prolonged absorption appears to approach nature's method of continuous insulin secretion. The Hagedorn investigators, basing their conclusions on a carefully treated group of diabetic patients, have shown these encouraging results with protamine insulin: a more prolonged insulin action without increasing the number of injections, diminished blood sugar fluctuations, and reduction of the risk of developing marked hypoglycemia reactions. They have found that the effect on the blood sugar is less rapid but more persistent than with ordinary insulin, so that normal blood sugar may be attained even in some cases of severe diabetes. Such results have been confirmed by Root and his co-workers,³ Conlin,⁴ Best, Kerr, Campbell and Fletcher,⁵ and Sprague and his co-workers.²

What studies have been given to the action of protamine insulin on the absorption of the dextrose of the food appear to have been made for the purpose of rearranging the carbohydrate content of the day's allowance so as more nearly to meet the rate of absorption of the protamine compound. Thus Hagedorn's patients were given diets averaging a total of 2,300 calories, containing about 70 Gm. of protein and 100 Gm. of carbohydrate. By giving protamine insulin in the evening, better results were obtained, the diet being divided so that 40 per cent of the carbohydrate portion was taken at breakfast, 40 per cent at lunch and 20 per cent at dinner. Sprague obtained better results by providing diets containing from 160 to 170 Gm. of carbohydrate, apportioned approximately 20 per cent, 40 per cent and 40 per cent, because the slow development of the maximal effectiveness of protamine insulin when given before breakfast makes that division desirable. Root,³ advocating higher carbohydrate diets, from 130 to 241 Gm., also obtained better results by rearranging the diets so

Miss Mary McNulty, B.S., was chief dietitian under whom the diets were prepared. Drs. Philip Duca and Albert Schwartz gave valuable assistance in carrying out the details of the experiment, Frank Cateca and Miss Marian Hanahan performed laboratory examinations.

Dr. F. B. Peck of Eli Lilly & Co. and Drs. H. Sidney Newcomer and J. A. Morrell of E. R. Squibb & Sons placed at the disposition of the author sufficient quantities of protamine insulin to enable him to undertake and complete the experiments, as well as to maintain an increasing number of patients on the combined insulin therapy.

that larger portions of carbohydrate were given for breakfast and lunch and smaller for supper, as in Hagedorn's method.

In spite of the fact that the slow absorption of protamine insulin causes a delayed action, and ordinary insulin, more rapidly absorbed, has immediate effects, the various investigators contend that both types of insulin should be given before meals, irrespective of the rate of absorption of the dextrose of the food or type of diet. They advocate that protamine compound be given from sixty to ninety minutes before meals,³ thereby allowing more time for it to act on the fasting blood sugar, while the ordinary insulin be given from fifteen to twenty minutes before meals also.

POWER OF OXIDIZING THE DEXTROSE OF THE MEAL

Confronted by the fact that protamine insulin is slow acting, I decided to study (1) its effect on the fasting blood sugar during the interval between the time of its injection and the eating of the meal; (2) its rate of action on the increased blood sugar throughout the

tion of the breakfast, then every half hour for two hours, and every hour for two hours; then lunch was given, which contained the same proportions of protein, fat and carbohydrate as the breakfast. Immediately on completion of lunch a blood specimen was obtained for sugar estimation followed again by another in an hour. Protamine insulin, being a slower acting compound, was given one-half hour before breakfast to the group under study. The doses of protamine insulin given varied from 20 to 60 units at each injection.

The ordinary insulin group (four patients) was also given a total of eleven blood sugar estimations. Thus a fasting blood specimen was obtained in each of the four patients in the group followed by a calculated and carefully weighed breakfast; another blood specimen was obtained immediately on completion of breakfast and again in from fifteen to twenty minutes, followed immediately by the designated dose of ordinary insulin. A blood specimen was obtained for sugar estimation in from fifteen to twenty minutes, then every half hour for one and one-half hours, and again every hour for

period of absorption of the dextrose of the meal; (3) its effect on the blood sugar at the end of the absorption of the meal, usually at the end of from three to four hours, the average time required for emptying the stomach;⁴ (4) the resultant blood sugar level just prior to the succeeding meal; (5) the effect of absorption of the dextrose of the succeeding meal on this resultant blood sugar level at the end of the first hour after eating; (6) the effect of protamine insulin on the blood sugar during the interval between the patient's retiring and rising (i. e., midnight to 7 a. m., or the resting interval); (7) the result of the foregoing observations as compared with another group of diabetic patients to whom ordinary insulin was administered under analogous conditions; (8) the optimum time to administer protamine insulin in relation to the absorption of the dextrose; (9) whether it should be given alone or as an aid to ordinary insulin, and (10) the most effective clinical application of my observations. As a control, I also examined diabetic patients to whom no form of insulin had been administered.

In order to make these observations, eleven blood sugar estimations for each patient were taken in both the protamine insulin group (four patients) and the ordinary insulin group (four patients) during the meal period. The specimens of blood were obtained from the vein and examined for dextrose according to the Folin-Wu method. Thus for the protamine group a fasting blood specimen was obtained followed immediately by hypodermic injection of a designated number of units of protamine insulin; one-half hour later another blood specimen was taken, followed immediately by breakfast; again a blood specimen immediately on comple-

two hours. Lunch was then served, followed immediately on its completion by the obtaining of another specimen of blood, and again in an hour. This group was given ordinary insulin from fifteen to twenty minutes after meals⁵—not before—as had been our practice with all diabetic patients requiring insulin who came to our diabetic dispensary or ward. Doses given to each member of the group varied from 16 to 60 units.

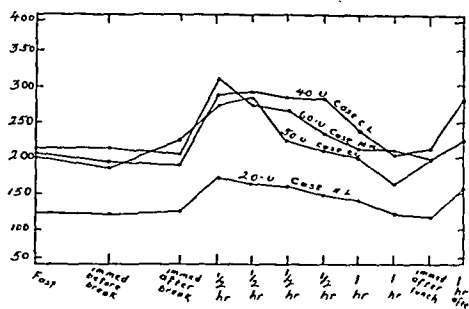

Chart 1.—Protamine insulin group (meal period).

The diets contained all the essential nutrients present in natural foods. We prescribed higher carbohydrate diets, varying from 100 to 180 Gm., proteins from 60 to 80 Gm. and fats from 80 to 100 Gm. for the total day. The quantities were divided into three equal portions so as not to vary from the established habits of the patients: breakfast containing one third of the day's total allowance of protein, fat and carbohydrate, and lunch one third. None of the patients had suffered previously from such gastro-intestinal disturbances as might interfere with the proper absorption of the food.

6. Rehlfuss, M. E.: Proteins versus the Carbohydrates: An Inquiry into Their Gastric Digestion, J. A. M. A. 103: 1600 (Nov. 24) 1934.

7. Sindoni, Anthony, Jr.: Optimum Time to Administer Insulin, Arch. Int. Med. 57: 949 (May) 1936.

During these examinations the patients were well occupied and showed no mental disturbance. The patients who had been treated by insulin previously to our studies were made to discontinue the therapy for three days before we examined them. Both forms of insulin were given for breakfast; neither was given for lunch. All the patients under examination were from the diabetic clinic and ward of the St. Agnes Hospital.

For clarification we tabulated each group. In the experiments outlined in table 1 we found that when protamine was given before breakfast at the end of the first half hour interval there was a very slight decrease in the fasting blood sugar as compared with the original fasting level. This was found to occur in all four cases. This is probably due to the little absorption of the insulin of the protamine compound and clearly indi-

of his food intake, will maintain the blood sugar at a constant normal level, except perhaps after meals, when it is slightly elevated, but always within the normal physiologic limit.

Next we proceeded to determine the effect of ordinary insulin on the blood sugar during the absorption of a meal as compared with protamine insulin. In prescribing ordinary insulin we gave it within fifteen to twenty minutes after meals⁷ during the inception of absorption of the dextrose of the meal. The dosages of ordinary insulin varied from 16 to 50 units. Diet proportions were similar to those given the protamine patients (table 2). This is graphically illustrated in chart 2.

The interesting fact revealed following these observations was that ordinary insulin is absorbed with extreme rapidity. The ordinary insulin, as compared

cates its slow absorption and action. Immediately on completion of the breakfast the blood sugar was slightly increased in two cases and slightly decreased in the other two, as compared with the blood sugar at the end of the one-half hour fasting interval when protamine insulin was given. But in the next half hour, and for three hours, the blood sugar of all the patients in the protamine insulin group rapidly increased above the original fasting level to a new high peak, after which it began to decrease at the end of the absorption. This is graphically illustrated in chart 1.

It appears from these observations that the height or level of the blood sugar and its persistence following the absorption of the carbohydrate of the meal depends in all probability on the amount and rate of absorption

with the protamine insulin, was better able in all the cases in the group to oxidize the rapidly absorbed dextrose of the meal, causing a rapid oxidation of the dextrose so that a normal or slightly below normal blood sugar level was maintained for from two to two and one-half hours before the next meal (lunch). It appears from these observations that the patients received the beneficial effects of the rapid oxidizing action of the insulin on the dextrose throughout the absorption period of the breakfast by maintaining a nearer-to-normal blood sugar level as compared with the protamine insulin group. With the next meal (lunch) the beneficial effects of the insulin on the metabolic system were still evident in the reduced level of the blood sugar an hour after lunch as compared with the blood sugar level an hour after breakfast when insulin was administered.

We then proceeded to determine the effect of the protamine insulin, as compared with the ordinary insulin, on the blood sugar during the resting interval: the period when the patient retires, from 12 midnight to 7 a. m., when no food is given. These patients under examination had been confined to bed several days previously to our examination. The purpose, of course, was to make certain that no previous disturbance would interfere with our examination. When studies with protamine insulin were made, a blood specimen was obtained at midnight, followed immediately by a dose of protamine insulin; then another blood specimen was taken at 4 a. m. and again at 7 a. m. for sugar estimations. Similar tests were made with ordinary insulin.

Three groups of three patients were examined—one group of three patients with protamine insulin, the other group of three with ordinary insulin, and finally a control group of three patients to whom no form of insulin was administered but blood sugar specimens were obtained at midnight, 4 a. m. and 7 a. m.

Thus for clarification the results obtained in each group of patients during the resting interval were tabu-

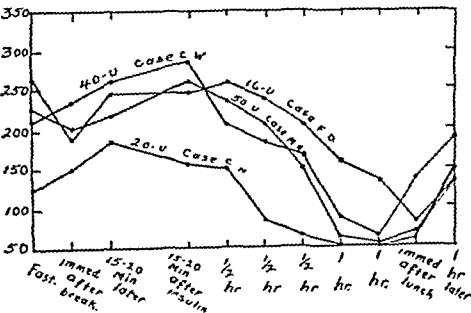

Chart 2.—Ordinary insulin group (meal period).

of carbohydrate as well as on the exogenous or artificial insulin, the degree of damage to the insulin-secreting mechanism (the islands of Langerhans) and the state of liver function (eliminating any gastro-intestinal disturbance that might interfere with its digestion or absorption). The protamine insulin compound with the endogenous insulin was still insufficient to oxidize the rapidly increased dextrose of the meal as absorption continued, resulting in rapidly increased blood sugar. A normal individual, irrespective of the amount

lated. For the protamine insulin group dosages varied from 16 to 30 units (table 3). This is graphically illustrated in chart 3.

The slight protamine insulin action occurred from midnight to 4 a. m. and increased slightly from 4 a. m. to 7 a. m., thus emphasizing the delayed, slow and prolonged insulin action.

TABLE 3.—Protamine Insulin Group (Rest Interval)

With the ordinary insulin the reduction of the blood sugar was more pronounced, as shown in table 4. The dose of ordinary insulin varied from 10 to 30 units.

Chart 4 illustrates the steep reduction of the blood sugar caused by the ordinary insulin as compared with the slight, slow, "somewhat straight line" decline of the blood sugar caused by the protamine insulin. With

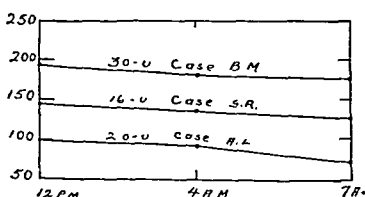

Chart 3.—Protamine insulin group (rest interval).

ordinary insulin the maximum effects on the blood sugar were obtained from midnight to 4 a. m. From then on it appeared to lose its effectiveness. What reduction of the blood sugar occurred after 4 a. m. was probably

due to the beneficial effects produced on the liver and muscle glycogen function by the insulin action from midnight to 4 a. m.

In the control diabetic group in which no form of insulin was administered there was a gradual increase in the morning blood sugar above the midnight level (table 5). On the basis of these clinical studies I agree with Hagedorn and other investigators that, when protamine insulin compound is given hypodermically, a slow but continuous disintegration of the compound takes place which slowly liberates the active insulin. The duration of the disintegration and the rate of absorption of the active insulin have been affected somewhat by the practice of adding zinc to insulin compound⁸ for the purpose of further prolonging the protamine insulin action. Other factors affecting its action are individual susceptibility to the compound, age, the duration of the diabetes and the condition of the cardiovascular system.

Indiscriminate use of the compound may subject the patient to unfavorable disturbances or symptoms. Lawrence⁹ already has shown its inability to control the hyperglycemia of the meal caused by the dextrose of high carbohydrate diets. Gray¹⁰ also appears to be disappointed with protamine insulin compound. Allen¹¹

speaks of more violent fluctuations of the hyperglycemia and hypoglycemia with protamine insulin than with the old insulin. Fortunately, we have had no cases of protamine insulin hypoglycemia reactions in patients with extensive premature cardiovascular sclerosis. I feel that if such reactions did occur in such patients they would probably be more serious than with the ordinary insulin because of their longer duration, since hypoglycemia reactions, as shown by Ernstene and his co-workers,¹² have a deleterious effect on the myocardium.

PROBABLE ULTIMATE EFFECTS ON THE DIABETIC METABOLISM

Forsgren¹³ has shown by histochemical methods that the carbohydrate metabolism of the body undergoes a cyclic change. Agren and his co-workers¹⁴ also found a rhythmic change in the liver with alternate glycogen production and bile secretion. Through a series of numerous experiments, Higgins and his co-workers¹⁵ have shown that the food intake determines the cyclic changes that occur in the liver following feeding. They

TABLE 4.—Ordinary Insulin Group (Rest Interval)

were able to vary the cyclic changes in liver and muscle by changing the feeding time. This is the opposite view of Möllerström.¹⁶ Therefore isn't it important to have the dextrose of the meal properly oxidized, so as to effect proper glycogen storage and help to maintain normal cyclic changes in the liver and muscles? I believe that the more complete the oxidation of dextrose of the meal in diabetes, the more normal will be the blood sugar throughout the period of its absorption, the better the glycogen storage and function of liver and muscle, and hence the better the metabolic equilibrium. There would result in all probability fewer diabetic complications such as gangrene, coronary disease or visual disturbance. Premature arteriosclerosis in diabetes would be further delayed, approaching probably the normal time in its inception. A large percentage of the insulin patients would be able to discontinue insulin therapy.

Thus in a group of eighty-five diabetic patients who had had treatment previously to coming to our diabetic clinic, I was able when administering insulin after meals to effect such a reduction of the increased hyperglycemia of the food that discontinuance of insulin therapy resulted in 60 per cent of the cases, reduction of the total daily dosages resulted in 20 per cent, while in the remaining 20 per cent all of them of such severity, the insulin dosage was slightly increased.¹⁷

The slowly acting protamine insulin appeared to have little or no effect on the rapidly absorbed dextrose of the higher carbohydrate meal. However, within an hour before lunch the blood sugar of the protamine group was slightly reduced below the original fasting sugar, owing in all probability to the fact that absorption of the food had been completed, an absorption coupled with a slight insulin absorption and action from the protamine compound. But the blood sugar rapidly increased, rising to abnormal heights immediately after lunch and an hour later as recorded by the blood sugar estimation, perhaps continuing to increase until the end of absorption. The fact remains that absorption of protamine insulin is too slow to oxidize the rapidly absorbed dextrose of the meal for from two to three hours after eating.

A. L.	♂	66	138	6 yrs.	None	Both	158	160	166

What will be the immediate effect on the metabolic system of these sudden increases in blood sugar to abnormally high levels maintained perhaps for two or more hours? What would the latent effects be if the increased hyperglycemia were repeated after each meal, extended over periods of months and years, even though the fasting blood sugar was normal and in spite of the fact that the patient shows no immediate external manifestations? The answer to these questions will, of course, depend on the height of the abnormal blood sugar level, the duration of this abnormal level during the absorption of the food, the age of the patient, the condition of his cardiovascular system at the time of its onset, the state of his liver function and the duration of his diabetes.

Probably the immediate effects of this incomplete oxidation of the carbohydrate of the meal are a slight interference with the liver function, especially its rhythmic action—glycogen production and bile secretion. If the incomplete or disturbed carbohydrate oxidation continues after each meal and is extended over a period of months and years, will not the disturbed metabolism produce marked effects, however latent? These latent effects in all probability manifest themselves in premature sclerotic changes in diabetic patients.

The chemical disturbances that are responsible for these premature changes are still in doubt. Patchy distribution of the lesions in arteriosclerosis suggests some preceding local condition in the involved areas which

favors the precipitation of lipoids.¹⁸ Warren¹⁹ is of the opinion that the effect of the high sugar concentration and its fluctuation in persons with diabetes possibly lead to swelling of the intimal ground substances through changes in osmotic pressure and thus favor lipid inhibition. It is generally believed that, when the blood sugar rises following a meal, the cholesterol rises also, the continued hyperglycemia leading to disturbance of the cholesterol metabolism.²⁰ Why isn't the increased hyperglycemia and its fluctuations, which occur invariably during the absorption of the meal and are repeated after each meal, accompanied probably by a rise or disturbance in cholesterol, the factors most likely to produce the local condition of the arterial walls? Since the consensus is that a disturbance in cholesterol metabolism plays an important part in the etiology of arteriosclerosis, isn't it justifiable to infer that the incomplete oxidation of dextrose of the meal may disturb the rhythmic or glycogen function of the liver and help to disrupt cholesterol metabolism as well as to effect vascular damage favoring precipitation of lipoids and eventually bring about premature sclerotic changes? Perhaps such disturbance may not necessarily manifest itself by hypercholesteremia but by disturbed cholesterol metabolism, even though blood cholesterol is normal; perhaps over a long period of months or years it will help to bring about premature sclerosis. Duff²¹ states that arteriosclerosis in a man can and usually does develop without deviation of the cholesterol content of the blood beyond the normal limits of variation.

Recently there has been a change in the ratio of carbohydrate and fat in the diets to a high carbohydrate and low fat content. Such a change of ratio has caused, according to Rabinowitch,²² Joslin²³ and others, a delay in the period of inception of arteriosclerosis. But in spite of this it still makes its inception prematurely in diabetic patients as compared with the nondiabetic.

In view of the fact that sclerotic changes are prevalent prematurely in diabetic patients, there are reasons enough to believe that the extent of the disturbed cholesterol metabolism, as well as the sclerotic changes, will depend on the state of the carbohydrate metabolism. Thus there are patients who appear to control their diabetes for years without artificial insulin because they have a normal fasting blood sugar. This is in all probability due to the fact that they possess sufficient circulating endogenous insulin to metabolize their own carbohydrate. But for an interval of perhaps one to three hours following each high carbohydrate meal the blood sugar becomes increased above the normal level, probably causing a rise or a disturbance of the cholesterol metabolism. If this increased hyperglycemia should be extended over a period of years, it would more than likely cause a disturbance of glycogen function of liver and muscle and various other of the metabolic disorders or complications so common in diabetes. To cite one of the many cases that have come under observation:

A man, aged 66, weighing 187 pounds (85 Kg.), who suffered from diabetes for at least seven years, had been treated by his physician with diet and insulin. His diet was liberal;

in fact it was increased at various intervals because of his frequent low fasting blood sugar. When he first was examined three years previously his fasting blood sugar was 113 mg.; two hours after meals it was 190 mg., in spite of the fact that his blood cholesterol was increased only within the normal range. Three months later he was admitted to the hospital suffering from diabetic gangrene in the little toe of the left foot and retinal hemorrhage in both eyes.

Even though his fasting blood sugar was normal, he was not properly oxidizing the dextrose of the meal, as was evidenced by the increased hyperglycemia two hours after meals. This condition had perhaps con-

These observations emphasize perhaps the fallacy of attempting to determine by fasting blood sugar estimations only the oxidizing power of the diabetic patient for dextrose. Blood sugar estimations during the absorption of the food would demonstrate more clearly the patient's oxidizing power and state of progress and the state of the insulin secreting mechanism, as well as that of the liver glycogen or its rhythmic function.

Thus with these facts in mind I felt that protamine insulin should be prescribed only as an aid to ordinary insulin and then only when the patient retired or in the morning after breakfast following the ordinary insulin.

TABLE 6.—Patients on Combined Insulin Therapy (Protamine and Ordinary)

tinued over a period of years and finally manifested itself by marked premature sclerotic changes. Perhaps the disturbance of cholesterol in the case cited, though not amounting to an abnormal increase, was more pronounced with the increased hyperglycemia. And perhaps the hyperglycemia extending over a period of months and years hastened or probably aided in causing the vascular changes. Thus if increased blood sugar fluctuation above the normal level is considered

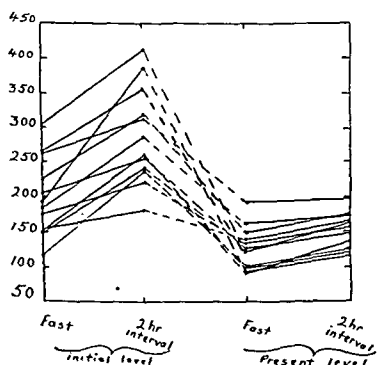

Chart 5.—Patients on combined insulin therapy (protamine and ordinary).

a possible factor in producing an injury to the arterial walls (as it does, according to Warren), increased cholesterol, according to Duff, or disturbed cholesterol metabolism will probably accelerate the development of arteriosclerosis. This, of course, is in agreement with many observers who find increased or disturbed cholesterol accompanying marked sclerosis of diabetic patients.

The reasons for advocating protamine insulin after breakfast following the ordinary insulin are: 1. When protamine insulin was given one-half hour before breakfast it appeared to have little or no effect on the fasting blood sugar or on the blood sugar during the first four hours of the resting interval. 2. The effects of protamine are too delayed to oxidize the rapidly increased hyperglycemia caused by the breakfast of those on the higher carbohydrate diets. 3. No apparent advantage is gained by prolonging the interval between protamine insulin injection and the time of eating breakfast; probably, on the other hand, it increases the discomfort of the patient. During the interval from breakfast to supper, ordinary insulin after meals⁷ should be given because its rapid absorption and action as well as its short duration results in a more complete oxidation of the rapidly absorbed dextrose of the meal. Page²⁰ states that ordinary insulin itself, while sharply lowering the blood sugar, tends also to reduce the cholesterol within a period of three hours after its administration to rabbits. In advocating the combined insulin therapy, I feel that by its use the elevation of the blood sugar caused by the absorption of the dextrose of the meal could be reduced more nearly toward the normal level.

CLINICAL APPLICATION OF THE OBSERVATIONS

For clinical trial and treatment a group of patients was selected for whom we prescribed combined protamine and ordinary insulin. Our purpose was to deter-

mine their effects on the increased hyperglycemia of the food as well as on the fasting blood sugar level. The ages of the patients varied from 11 to 74 years; the duration of the treatment varied from four weeks to six months. A large number of the patients had been treated by diet and ordinary insulin previous to coming under our care. Many suffered from various forms of complications in spite of the fact that they had a somewhat normal fasting blood sugar on their initial examination. Table 6 explains the results achieved in a few of the many cases, graphically illustrated in chart 5.

The interesting facts from our observations revealed that many of the patients, in spite of the normal fasting blood sugar level on the initial examination, showed a marked increase during the absorption of the food even though they had been previously treated by diet, insulin, or both. Such patients are probably among the large group who suffer from marked premature sclerotic changes and diabetic complications.

An important fact observed among the few of our patients on the combined insulin therapy was that in spite of the low blood sugar immediately before breakfast and also at the end of the two hour interval, which would ordinarily produce symptoms of hypoglycemia in the average diabetic patient, they felt well. Some patients at the end of the two hour interval had a blood sugar level as low as 50 mg. without any apparent discomfort.

SUMMARY OF OBSERVATIONS

1. Incomplete oxidation of the dextrose of the meal, as evidenced by the increased hyperglycemia occurring after each meal, extended over a period of months and years may bring about a disturbance in the cyclic glycogen function of the liver and muscles (Möllerström, Forsgren, Higgins, Agren and his co-workers) and alterations in the arterial walls (Warren), though perhaps these alterations are brought on by an injury of some kind (Duff). These alterations in the arterial wall precede the precipitation of lipoids²⁴ and initiate the premature sclerotic changes so common in diabetic patients and increase in or disturbance of cholesterol metabolism, which accelerates the development of premature sclerotic changes.

2. Blood sugar estimation following meals during its absorption would reveal the extent as well as the progress of the patient's oxidizing power for dextrose.

3. A fasting blood sugar estimation is not a reliable and complete index to a patient's oxidizing power of dextrose or his progress.

4. Protamine insulin compound is absorbed too slowly to oxidize the rapidly absorbed dextrose of the high carbohydrate diets advocated today; hence it is unable to control the increased hyperglycemia.

5. Ordinary insulin within fifteen to twenty minutes after meals, because of its rapid absorption and action, is superior to protamine insulin to oxidize the rapidly increased hyperglycemia of the higher carbohydrate meal, and hence it is better able to reduce the increased hyperglycemia.

6. It is not advisable to give protamine insulin before meals because (1) if given a half hour before breakfast it has little or no appreciable effect on the blood sugar; (2) a longer interval between the injection and the eating of a meal may subject the patient to much unnecessary discomfort; (3) it should not be given during the

day with the thought of affecting the dextrose of the following meal; (4) no advantage is gained in any case, since the rapid absorption of the dextrose of the meal will rapidly increase the hyperglycemia; (5) the maximum effects of protamine insulin are usually obtained several hours or, occasionally, as has been reported, from three to four days after the time of injection.

DISADVANTAGES OF PROTAMINE INSULIN

1. Because of its slow absorption and action, protamine insulin compound cannot control the hyperglycemia of the high carbohydrate diets advocated today or the increased hyperglycemia caused by such diabetic complications as acidosis, coma, infections or gangrene.

2. Protamine insulin, being slow acting, may involve the physician in the error of giving too frequent injections or too large doses in his effort to reduce quickly the blood sugar in a patient with severe or moderately severe diabetes. He may find that he has produced cumulative effects having such serious consequences as a continuous mild hypoglycemic reaction or one sufficiently severe as perhaps to prove fatal in advanced heart disease.

3. Patients on protamine insulin, aware of its unfavorable action—such as its cumulative effects—may become self conscious or fearful of its slow-acting hypoglycemic reaction. This may cause them to eat more or less continuously at the first sign or symptom of uneasiness, which may not infrequently be a hypoglycemic reaction. Then again they may fall into a mild mental confusion and, not infrequently, into unconsciousness without much warning.

4. After protamine insulin is given, the prolonged insulin effect may continue when perhaps not much insulin action is desired—at the completion of absorption of the meal. Thus, normally, increased insulin secretion and action is desired after meals during its absorption; less is desired after its absorption. When much insulin secretion and action are desired during absorption of the meals, protamine insulin is too slow or insufficient; when less is desired on completion of absorption of the meal, protamine insulin may be too rapid or too excessive. Perhaps a patient for some reason is forcibly detained in some locality, which makes it impossible for him to obtain his required proportioned meal. What effect will protamine insulin have on him, especially when he knows that he has had a protamine insulin injection the night before and that a hypoglycemic reaction is possible? It would probably aggravate his mental state and help the simulation of hypoglycemic symptoms.

5. To use two different preparations of insulin and to inject the two separate preparations at different times of the day in relation to the absorption of the food may be confusing to diabetic patients.

6. Protamine insulin is unstable after six months.

ADVANTAGES OF PROTAMINE INSULIN

1. With one injection of protamine insulin when the patient retires, the blood sugar—as shown by our experiments during the resting period or the interval on retiring and arising—is slowly reduced, indicative of the delayed, slow, prolonged but continuous insulin action. This effect will avoid the necessity of awakening the patient who previously required an early morning dose of ordinary insulin at from 3 to 4 a. m.

2. When protamine insulin is prescribed as an aid to ordinary insulin in severe or moderately severe diabetes

24. Leary, Timothy: Experimental Atherosclerosis in the Rabbit Compared with Human (Coronary Atherosclerosis), Arch. Path. 17:453 (April) 1934.

it will more completely oxidize and reduce the marked hyperglycemia of the food than the single ordinary insulin.

3. Such combined insulin therapy (ordinary and protamine insulin) will frequently reduce the total number of units per day, shorten the period of insulin therapy and further increase the well being as also the resistance of the patient, as already shown by our experiments.

4. Surgical wounds as well as infections respond better on the combined insulin therapy.

CONCLUSION

1. Since protamine insulin is inadequate to oxidize the rapidly absorbed dextrose of the meal, it should not be prescribed alone but only as an aid to ordinary insulin. Together they form an ideal insulin therapy in diabetic patients requiring large doses of ordinary insulin. Protamine insulin, if indicated, should be given on retiring and if necessary after breakfast, immediately following the ordinary insulin, which is given within from fifteen to twenty minutes after meals. Between meals the dextrose of the meal that escaped oxidation of the ordinary insulin may be oxidized by the slow, continuous action of the protamine insulin. This combined form of insulin therapy approaches more nearly the natural insulin secretion and action in oxidizing the increased blood sugar caused by the absorption of the carbohydrate of the meal than probably any single insulin preparation so far advocated.

2. This combined insulin therapy, ordinary insulin and protamine insulin, is advocated in:

- (a) Any type of diabetes requiring large doses of ordinary insulin.
- (b) Preoperative and postoperative cases.
- (c) Acidosis and coma cases.
- (d) Patients with marked fluctuations of blood sugars.
- (e) Elderly diabetic patients with advanced sclerosis of the cardiovascular system—though in these cases the greatest care should be exercised.
- (f) Cases complicated with infections.

3. Fasting blood sugar estimation (before breakfast) alone, as practiced by the majority of physicians, is no complete reliable index to the progress of the patient's diabetic condition or oxidizing power of carbohydrate.

4. A blood sugar estimation two hours after meals gives a better index to a patient's oxidizing power.

5. It is advisable, therefore, in order to obtain a better index to the patient's oxidizing power of carbohydrate, as well as his progress, to obtain a fasting blood sugar estimation as well as one after meals, i. e., a two hour interval. The latter examination should be repeated in preference to the blood sugar estimation before eating of the meal at various intervals, so as better to estimate and adjust the insulin dose and diet. This will help to obviate much of the blood sugar fluctuation and insulin reaction and to control better the metabolic state of the diabetic patient. It will also be more convenient for the patient to come after he has had his breakfast instead of before.

6. With the combined insulin therapy (ordinary insulin and protamine insulin) much will be accomplished; i. e., a better and more complete oxidation of the hyperglycemia of the food resulting in nearer to normal sugar curve after meals, a smaller likelihood of disturbances of cholesterol metabolism, a better glycogen storage in liver and muscles and, hence, an improvement in their rhythmic function. This will

result in a better metabolic equilibrium and, in all probability, help in further delaying the period of inception of premature arteriosclerosis.

7. Patients should be hospitalized before attempting the use of protamine insulin. The purpose of course, in addition to other factors, is to test their reaction and susceptibility to the compound.

8. Considering the advantages as well as the disadvantages of protamine insulin and ordinary insulin, I feel that ordinary insulin therapy, if properly administered in relation to dextrose absorption, is still the rock foundation of insulin therapy in diabetes and superior to protamine insulin, especially in those on high carbohydrate diets. The combined insulin therapy (ordinary and protamine insulin) has better helped to solve the problem of reducing the marked hyperglycemia of the food than any single insulin preparation advocated today. Such reduction of the food hyperglycemia approaching the normal curve will result in delaying premature arteriosclerosis, help to prolong the span of life and period of usefulness, and increase resistance to infection.

9. If a diabetic patient is responding favorably with small doses of ordinary insulin after meals that maintain a blood sugar that is within the normal level two hours after meals, it is not advisable to use protamine insulin.

1315 Pine Street.

INCIDENCE OF CORONARY SCLEROSIS AMONG PHYSICIANS

AS COMPARED WITH MEMBERS OF OTHER
OCCUPATIONS

HARRY L. SMITH, M.D.

ROCHESTER, MINN.

It has long been believed that the incidence of coronary sclerosis was higher in certain vocations than it was in others. Writers formerly observed that it was relatively rare in the public wards of hospitals as compared with the private wards. Osler observed that it was not a condition affecting the working classes. Colbeck concluded that it was uncommon among blacksmiths, soldiers and other laborers. Attention has been called to the importance of stress, strain and worry as predisposing causes of this disease. It has been described as a disease of the "intelligentsia." Several writers have called attention to its prevalence among physicians, and it has even been described as the "disease of doctors." Some writers have expressed the opinion that it was evidence of eminence and that if a physician acquired the disease it was proof that he had reached the height of professional success. In a series of cases reported by Osler, a large proportion of the patients were physicians. Many members of the medical profession have been victims of coronary sclerosis. Some of the distinguished members of the profession who have succumbed to this disease are John Hunter, Charcot, Nothnagel and Pepper. Others who recently have been victims are Martin, Howard, Saylor, Manges, McVicar and Funk.

This study consists of a comparison of the incidence of coronary sclerosis among physicians, bankers, lawyers, clergymen, laborers and farmers among the clientele of the Mayo Clinic. I examined the consecutive

clinical records of 307 physicians, 300 bankers, 304 lawyers, 306 clergymen, 306 laborers and 308 farmers and compared the incidence of coronary sclerosis in each group. There were thirty-three instances of coronary sclerosis among the physicians, sixteen among the bankers, fourteen among the lawyers, fourteen among the clergymen, eight among the laborers and eight among the farmers (table 1). The criteria for the diagnosis were the same in all the groups. Therefore I feel that the error in diagnosis should be the same in all groups. The average age of the patients, which was about the same for all groups, was 52.8 years for the physicians, 51.5 for the bankers, 52.8 for

dence (12.8 per cent) in the age decade 60-69 years. It should be kept in mind, however, that when the entire series of patients is divided into subgroups according to occupation and age there are only relatively small numbers of cases from which to calculate rates, and these are therefore subject to considerable statistical variability. The figures given are intended only to provide a general comparison of the incidence rates for the members of various occupations studied at different decades of life.

COMMENT

It is interesting to speculate why there is a much greater incidence of coronary sclerosis among physicians than among the other groups. I fully appreciate that in any study of this nature the figures and comparisons are subject to considerable statistical error, but the rate of incidence is so strikingly different in the various groups that I believe the difference is significant. For the group as a whole the highest incidence of coronary sclerosis is found among the physicians. In this group it is more than double what it is in any other occupation. It is four times as great among physicians as it is among laborers and farmers, and it is about twice as great among bankers, lawyers and clergymen as it is among laborers and farmers.

One might argue that the groups of patients studied here do not give a fair representation of the various groups of patients as they actually exist in various localities. This may be true, and this criticism may be made of the patients of any hospital or clinic because they are somewhat specialized and selected groups, and the percentages of members of the various occupations that constitute the clientele of the clinic may be different than the percentages as they actually exist.

There is another factor which may have made a difference in the results obtained here. That is, the physician is more concerned about his heart than are members of the other groups, and he is likely to seek an examination on less provocation than do the members of the other groups. This may be partially true and

the lawyers, 52.2 for the clergymen, 50 for the laborers and 53.1 for the farmers. The average age for the different groups is about the same, with the exception of the laborers, and I do not believe that the difference in the average age of the patients in this group is significant. The fact that the individuals in this group were slightly younger than were the others may partially explain why the incidence of coronary sclerosis is less in this group.

I have given the incidence rates (percentage of total patients who had coronary sclerosis) by decades of age to 70 years or more (table 2). For the entire series of 1,831 patients it is interesting to note that the incidence of coronary sclerosis increases steadily with age to old age. In the age group 20-29 years there were no cases of coronary sclerosis. For the age period

60-69.....	66	10	15.2	57	6	10.5	75	3	4.0	59	7	11.9	63	2	3.2	39	5	12.8	359	33	9.2
70 or more.....	22	4	18.2	13	1	7.7	12	2	16.7	17	2	11.8	20	2	6.7	10	0	0	104	11	10.6
Total.....	307	33	10.7	300	16	5.3	304	14	4.6	306	14	4.6	308	8	2.6	306	8	2.6	1,831	91	5.1

30-39 years the rate was 0.5 per cent, for the period 40-49 years it was 2.5 per cent, for 50-60 years it was 5.9 per cent, for 60-69 years it was 9.2 per cent, and for the age period 70 years and more it was 10.6 per cent. When the individual occupation groups were considered separately, it is seen that at every decade of age the greatest relative incidence occurs among physicians. The bankers and lawyers come next in order, after that come the clergymen, and lastly come the farmers and laborers. This ordering holds only generally; at particular decades of age there are exceptions. Notably the laborers show a large relative inci-

it is possible that this factor may be partially responsible for the greater incidence of coronary sclerosis among physicians. However, there is another factor which I believe will at least partially, if not completely, offset this influence, and that is the fact that at the clinic we examine a great number of physicians each year who come to Rochester for other reasons than their health, such as to visit clinics, observe operations, do special work and accompany patients. This would not be true of the other groups.

Just why should the incidence of coronary sclerosis be so high among physicians? I believe the following

is at least a partial explanation: It has long been recognized that stress, strain, intensity of work and mental worries are factors in the production of coronary sclerosis. A physician's schooling is long and intensive compared with that of the average banker and business man. Undoubtedly a doctor has used up a great deal of nervous energy by the time he has finished school. Secondly, the nature of a physician's work is much more strenuous, and he has not only the responsibility of health but oftentimes of life itself in his hands. A physician's routine work, which includes ordinary obstetric cases with their complications, broken legs, severe cardiac diseases, scarlet fever and diphtheria among children and pneumonia among the aged, and the responsibility of the surgeons, which is probably greatest of all, is actually or nearly as intense as that of the banker when there is a run on his bank. In other words, what is a crisis for the banker and business man is more or less routine for the physician.

I believe that one can reasonably conclude from this study that occupation does influence the incidence of coronary sclerosis, that the incidence is lowest among those who do manual labor and highest among those who do mental work, and it would seem that it is highest of all among physicians.

PROSTIGMIN AS AN AID IN THE DIAGNOSIS OF MYASTHENIA GRAVIS

A. M. HARVEY, M.D.

AND

M. R. WHITEHILL, M.D.

BALTIMORE

Our object in this communication is to demonstrate the value of prostigmin as an aid in the diagnosis of myasthenia gravis. In the course of the study this drug was used with immediate but transient improvement in nine cases of the disease, and with neither subjective nor objective changes in fourteen cases of various neurologic disorders. The value of this drug in the treatment of these patients will also be discussed.

In recent years interest in myasthenia gravis has been stimulated by the discovery of new therapeutic agents and by metabolic studies. Walker¹ in 1934 reported the improvement that resulted from the subcutaneous injection of physostigmine salicylate. This drug was tried because it was thought that the disease might be due to a curare-like poisoning of the motor nerve endings or the myoneural junctions. Feb. 8, 1935, Walker demonstrated before the Clinical Section of the Royal Society of Medicine the improvement that occurred in one case with prostigmin, an analogue of physostigmine. In April 1935 she² reported this case. After a subcutaneous injection of 2.5 mg. of prostigmin, ptosis and ophthalmoplegia disappeared within five minutes. The maximum effect was reached in one hour, and there was a gradual return to the previous state over a period of from six to eight hours. Prostigmin was considered superior to physostigmine because of a less depressing effect on the heart, the less frequent occurrence of nausea and vomiting, and the safety of administration of larger doses. In March 1935

Laurent³ described improvement in seven cases with 2 cc. of prostigmin subcutaneously. He suggested that prostigmin might help in the diagnosis of early and slight cases. In May 1935 Pritchard⁴ reported seven cases treated with prostigmin. His results were similar to those noted by Walker.

Shortly after the present report had been submitted for publication, Viets and Schwab⁵ described a method of using prostigmin as a diagnostic test in myasthenia gravis. In five patients with the disease a rapid improvement took place in the symptoms and signs, while seven patients with other disorders showed only a slight response to the drug. Three cc. (1.5 mg.) of prostigmin and 0.6 mg. of atropine sulfate were injected simultaneously. Control injections with physiologic solution of sodium chloride gave no response. In a second report, by Viets and Mitchell,⁶ further experience with the use of the drug is presented. They have now tested eighteen patients with myasthenia gravis and twenty-seven patients with other diseases such as progressive muscular dystrophy, recurrent ophthalmoplegia, progressive bulbar palsy and postencephalitic Parkinson's disease. The technic which they use is as follows: The patient is given 3 cc. of prostigmin with 0.6 mg. of atropine sulfate and the objective and subjective improvement in muscle power is tested at the end of ten and thirty minutes and one, two, four, six and eight hours. The response is graded by 0 indicating no change, 1 slight, 2 moderate, 3 marked and 4 complete improvement. Estimating both subjective and objective response on this basis at each test, a total score of 56 is possible. In the eighteen patients with myasthenia gravis the average test score was 30, and in the other conditions 1. The injections were given intramuscularly.

Hamill and Walker⁷ reported the use of the drug in bulbar palsy, amyotrophic lateral sclerosis, alcoholic neuritis and traumatic neuritis. Some change was noted but it was less dramatic than that in myasthenia gravis.

Everts⁸ administered prostigmin in two cases of myotonia congenita with a pronounced myasthenic syndrome, one case of alcoholic polyneuritis in which recovery had been slow, two cases of postencephalitic Parkinson's disease in which myasthenia was a factor, a case of facioscapulohumeral myopathy, and one of amyotrophic lateral sclerosis. He stated that all showed some improvement, but no details are given as to the doses of the drug or to the type, degree and rapidity of the response.

The following is a brief abstract of nine cases of myasthenia gravis in which prostigmin caused definite improvement.

CASE 1.—L. K., a Negro girl, aged 17 years, single, was in the ward from Aug. 27 to Oct. 13, 1935. Her family history was negative and her past history was good. One month before admission there was difficulty in chewing food. One week later ptosis, thick speech, regurgitation of water through the nose, transient diplopia, and weakness of the arms developed. Physical examination showed bilateral ptosis, more marked on the left; weakness of the right lateral rectus; nystagmus when she looked to the side, up or down; weakness of the jaw muscles bilaterally; bilateral facial weakness, more marked on

the left, and weakness of the arms. She had the typical myasthenic electrical reaction. The Wassermann reaction was negative. The spinal fluid, urine and blood were normal. She was given subcutaneously 1.5 mg. of prostigmin and 0.6 mg. of atropine sulfate. Within ten minutes she was able to open her eyes wide and in twenty minutes the lips could be closed tight. She smiled and ate her lunch with ease. Diplopia disappeared. After thirty minutes the patient was laughing and expressed the desire to walk around. One hour later she was seized with violent abdominal cramps, which were relieved by more atropine sulfate. The beneficial effect gradually wore off after the first hour, and seven hours later her condition returned to its previous state. She was given 25 mg. of ephedrine sulfate and 7.5 Gm. of aminoacetic acid twice a day. On two further occasions 1 mg. of prostigmin produced striking improvement, and on a third occasion 0.75 mg. was given with only slight improvement. On discharge her condition was a little improved.

For ten months following discharge she did fairly well on aminoacetic acid and ephedrine. Her second admission was from March 24 to May 13, 1936. For two months before, the symptoms gradually increased. A few days before she contracted an infection of the upper respiratory tract and there was a more rapid exacerbation of symptoms. April 13, 1936, she was begun on prostigmin by mouth, 30 mg. three times a day. Combination of prostigmin with either aminoacetic acid or ephedrine did not seem to increase its effectiveness. For the following eight months there was distinct improvement. She was seen several times, and diplopia and slight ptosis were the only abnormalities remarked on. The effect of prostigmin orally became apparent about thirty minutes after it was taken and gradually decreased over two to three hours. Unless it was taken she was unable to eat or to be up. Her third admission was from Feb. 7, 1937, to the present time, and this was initiated by a cold accompanied by a generalized maculopapular rash. It is of interest that the first admission was preceded by a cold and a similar rash and that as a young child she had measles. During the first several days in the hospital there were frequent attacks of severe dyspnea during which respirations rose to 80 a minute. These attacks were promptly relieved by prostigmin, 1.5 mg. subcutaneously. They became less frequent, and now she is well maintained on prostigmin orally and ephedrine.

This represents a case that was improved for eight months by oral prostigmin and in which the acute episodes were satisfactorily controlled by this drug subcutaneously.

CASE 2.—L. L., a white man, aged 51, married, a farmer, was in the ward from Sept. 20, to Oct. 13, 1935. The family history was negative and the past history was good. For seven months there was blurred vision, for six and a half months diplopia and drooping of the right lid, and for six months drooping of the left eyelid. For five months his voice tired after he talked for from five to ten minutes; there was difficulty in swallowing toward the end of the meal, progressive weakness and fatigability, anorexia and constipation. All symptoms were more marked after exertion and improved after rest. He lost 30 pounds (13.6 Kg.) after the onset of the present illness. Physical examination showed bilateral lower facial weakness and loss of muscle tone. There was marked ptosis of both lids and complete paralysis of all eye muscles except the left lateral rectus. Tendon reflexes weakened rapidly on repeated stimulation. There was a typical myasthenic electrical reaction. The Wassermann reaction was negative. The spinal fluid, blood and urine showed no abnormalities. He was given 1 mg. of prostigmin and 0.6 mg. of atropine sulfate subcutaneously. Within three minutes ptosis decreased and in ten minutes the lids could be opened wide. In ten minutes the forehead could be wrinkled, and subjectively the heavy dull feeling around the eyes disappeared. Before the injection the sternocleidomastoid muscle began to weaken after twenty faradic stimulations. Ten minutes after the drug was injected the muscle contracted eighty times before weakening and in fifteen minutes more than 100 maximal contractions were obtained. A normal control showed weakening after 100 stimulations. The patient was given aminoacetic acid and ephedrine, but on discharge there was no improvement.

He was again seen in November 1936, at which time he still had severe symptoms. Prostigmin, 30 mg. three times a day by mouth, was given, but after three months of this treatment he did not notice any improvement in his symptoms.

CASE 3.—H. N., a white man, aged 64, married, merchant, was in the hospital from June 10 to July 15, 1935. He had enjoyed excellent health until Jan. 20, 1935. At that time he noticed diplopia, which was soon followed by bilateral ptosis, difficulty in swallowing, abnormal fatigue of the voice and weakness of the legs, arms and neck. He was better in the morning and worse at night, and exertion made the symptoms more marked. Physical examination showed bilateral ptosis and marked restriction of all the extra-ocular movement. The muscles of the face, jaw and neck were weak. After he counted to fifty his voice grew nasal. There was difficulty in swallowing. There was no anemia. The Wassermann reaction was negative. The urine showed a faint trace of albumin. The course was afebrile. June 11 he was placed on 25 mg. of ephedrine sulfate and 10 Gm. of aminoacetic acid three times a day. This was discontinued June 20. He was given from 1 to 2 cc. of prostigmin three or four times daily for three days. The response at first was very favorable. There was increased ability to swallow, to talk and to perform extra-ocular movements. The beneficial results decreased with the continued use of the drug, however, and for that reason its administration was discontinued. He was discharged unimproved and five months later died at home.

CASE 4.—M. A., a white woman, aged 33, single, whose first admission was from March 19 to July 10, 1931, had a negative family history and an excellent past history. Her present illness began three weeks before admission with the sudden development of diplopia. The past history was entirely negative for myasthenic symptoms. Physical examination showed a divergent squint with weakness of the left internal rectus and slight ptosis on the left. The pupils reacted to light and in accommodation. There was a slight left facial droop. The visual fields were normal. The Wassermann reaction was negative. Examination of the blood, urine and spinal fluid revealed no abnormalities. While she was in the ward the course was afebrile with a slight tachycardia. At this admission the picture was not entirely clear, and she was discharged with the diagnosis of (?) encephalitis, (?) myasthenia gravis.

From July 15, 1931, to Oct. 19, 1932, she was seen at frequent intervals in the neurologic clinic. During that time the left internal strabismus remained practically constant. The left ptosis varied. Ptosis developed on the right. At times there was a slight facial weakness. She stated that at times her voice was weak toward evening, and that on one or two occasions she regurgitated fluids through the nose. There was a slight but steady increase in general weakness. From June 21 to Oct. 19, 1932, she was given ephedrine sulfate, 25 mg. three times a day. During this time a typical myasthenic reaction was obtained on stimulation of the sternocleidomastoid muscle. She was lost sight of from Oct. 19, 1932, until her second admission, Oct. 22, 1935. During this time she had been receiving no ephedrine and had been fairly well. During this period there were attacks appearing from four to five times a month which were characterized by increasing weakness, difficulty in speaking and swallowing, and increase in diplopia. These symptoms were apparently brought on by exertion but also occurred spontaneously. Each attack lasted for several days. One week before the second admission she contracted a cold and five days later there was marked weakness, swallowing was very difficult and speech disappeared entirely. The afternoon of admission she began to gasp for breath. On examination she was very poorly nourished and poorly developed; she was sitting up in bed, her breathing was rapid and shallow, and she was using the accessory muscles of respiration. The facial muscles were weak and toneless. There was bilateral ptosis and weakness of the left internal rectus. Complete aphonia and generalized muscular weakness were present. The deep and superficial reflexes were sluggish and tired easily on repeated stimulation. There were many large rhonchi throughout both sides of the chest and an area of bronchovesicular breathing beneath the left scapula. The temperature was 102 F., the pulse 104 and the respiration rate 36. She was immediately given 2 mg. of prostigmin and 0.6 mg. of atropine sulfate subcutaneously. Within five minutes the respirations were stronger. In ten minutes she was able to cough up mucus. In fifteen minutes there was a noticeable decrease in ptosis and she was able to whisper. In twenty-five minutes she talked in a weak voice and was able to

swallow liquids. After two hours ptosis increased again, and the voice and respirations became weaker. Over the next forty-eight hours she was given from 1.5 to 2 mg. of prostigmin thirteen times. The effect at first lasted from four to five hours, but later the duration of the action was much shorter, so that injections were necessary every one to two hours for relief of the extreme respiratory difficulty. She was also given 15 mg. of ephedrine sulfate three times a day and 20 Gm. of aminoacetic acid daily. Despite prostigmin, ephedrine, aminoacetic acid and supportive measures, she died from what appeared to be respiratory paralysis forty-eight hours after admission.

CASE 5.—A white man, aged 29, married, a farmer, who was admitted to the Johns Hopkins Hospital from July 13 to July 17, 1936, and whose past health was good, about a year before admission began to have difficulty in enunciating, and this progressed until his speech became almost unintelligible. At times food was regurgitated through the nose. There was some weakness of the extremities and he tired easily.

The general physical examination was negative. There was slight ptosis of the left lid, which increased when the lid was held open more than a few minutes. The jaws were so weak that the patient had to hold up the mandible with his hand. There was slight bilateral facial weakness. The soft palate and pharynx were weak, and the voice was nasal. The tongue could not be protruded for more than a moment, and then only the tip extended beyond the teeth. There was some weakness in abduction of the arms at the shoulders. No atrophy or fibrillary twitchings were seen. Sensation was everywhere normal. The reflexes were intact.

Faradic stimulation of the left deltoid and sternomastoid muscles caused fatigue after ten feeble contractions. Galvanic reactions were much better, prompt, and not suggestive of a reaction of degeneration.

The patient was given subcutaneously 1.5 mg. of prostigmin and 0.6 mg. of atropine sulfate. Within five minutes there was decided improvement. Ptosis of the left lid disappeared, speech improved, the jaw could be closed firmly, the tongue could be protruded freely, and the left arm could be held firmly in abduction. The nasal voice persisted.

The patient was discharged on aminoacetic acid 10 Gm. three times a day, and prostigmin 30 mg. three times a day, both to be taken orally. The diagnosis seemed clearly to be myasthenia gravis.

CASE 6.—A white man, aged 53, complained of drooping of the right eyelid and of weakness. For about five weeks there was occasional diplopia. For three weeks there were gradual drooping of the right eyelid and weakness of the arms and legs. For two weeks there was difficulty in mastication and for three days in swallowing. All these symptoms were increased by activity and decreased by rest.

The general physical examination was essentially negative. There was marked ptosis of the right eyelid. The right eye was divergent, could not be moved medially, and could be turned upward only slightly. The left eye moved medially very little. There was generalized weakness, worse in the left hand. The weakness increased on repeated effort and improved on rest. Sensation was normal. There was no atrophy or fibrillary twitching. The reflexes were intact. Electrical stimulation of the right sternomastoid muscle gave a myasthenic response.

Prostigmin 1.5 mg. and atropine sulfate 0.6 mg. were injected subcutaneously. Within five minutes there was complete disappearance of the ptosis, marked improvement in the extra-ocular movements, and increase in the strength of the jaw and hand muscles.

The patient was discharged on prostigmin 30 mg. and ephedrine sulfate 25 mg., both orally, three times a day.

The diagnosis of myasthenia gravis was quite definite. The symptoms were much improved for a few weeks with the medication prescribed. However, after a few weeks the drug lost its effect and hypodermic injections were begun. Finally, even these gave no relief of symptoms and the patient died about three months after his first visit to the hospital.

CASE 7.—A white man, aged 45, complained of drooping of the eyelids. The past health was excellent. For seven months the right eyelid dropped, and for five months there was similar difficulty with the left lid. The ptosis was not constant, was increased by activity, and was relieved by rest. He did not complain of diplopia.

There was moderate ptosis of both lids. The ocular movements were almost all lost, there being only slight deviation with strong effort. The neurologic examination was otherwise negative.

Electrical stimulation of the right sternomastoid muscle gave a normal response.

Prostigmin 1.5 mg. and atropine sulfate 0.6 mg. were injected subcutaneously. Within five minutes ptosis disappeared and the extra-ocular movements were fairly well performed.

The patient was treated for a year with ephedrine sulfate 25 mg. three times a day by mouth. There was little improvement or progression in the ocular muscle weakness. Weakness did not develop in other muscles.

This represents a case in which the clinical impression of myasthenia gravis was confirmed by the prostigmin test but not by electrical reactions. The stimulation was probably tried on a muscle not involved by the myasthenic process.

CASE 8.—A white man, aged 47, was admitted twice to the Johns Hopkins Hospital for muscular weakness. His past health was good. His first admission was from Feb. 18 to March 18, 1935. Four and a half years before, double vision and weakness of the left leg began and continued with varying severity. Since then the right eyelid had drooped and there had been generalized weakness increased by activity.

The general physical examination was negative. There was slight ptosis of the right eyelid. The left eye could not be adducted beyond the midline. The voice weakened on counting 150 rapidly. Muscle strength in general was good, but the muscles tired easily. The clinical impression was myasthenia gravis, but there was some doubt about the diagnosis.

A myasthenic response was obtained on stimulation of the right sternomastoid muscle with the faradic current.

For a month after discharge he took aminoacetic acid and ephedrine without improvement. Muscular weakness increased so that he became bedridden, and he developed difficulty in swallowing and talking. On our advice he began taking prostigmin, 0.5 mg. subcutaneously each day. After an injection he stated that he could sit upright after fifteen to thirty minutes and felt much stronger for from two to three hours.

The second admission was from April 19 to May 14, 1936. At that time, in addition to the foregoing, there was bilateral partial ptosis and neither eye could be moved upward. There was diplopia in all fields. April 19, 1936, he was started on prostigmin 30 mg. by mouth three times a day. There was considerable increase in muscular power, so that he was able to sit up and eat without difficulty. For one day it was omitted and then he could not raise himself from bed. That day he was given subcutaneously prostigmin 1.5 mg. and atropine sulfate 0.6 mg. Within ten minutes he could raise himself from a supine to a sitting position, the ptosis disappeared, and there was much subjective improvement.

Since then he has continued on oral prostigmin. He has found it necessary to increase the dosage to 15 mg. from nine to ten times a day. If he exceeds 30 mg. at a dose, severe abdominal cramps result. If he omits a dose, muscular weakness renders him helpless. He has never been able to become ambulatory.

This represents a puzzling case in which the diagnosis of myasthenia gravis was strengthened by a positive reaction to prostigmin. Treatment with prostigmin orally undoubtedly caused much benefit, but the disease was of such severity that nontoxic doses brought about only partial relief.

CASE 9.—A white woman, aged 44, complained of weakness of the left side of the face and of the muscles of mastication, of about five months' duration. Her past health was excellent. When first seen, the only positive finding was slight weakness of the left facial muscles, involving especially the lower portion of the face. It was thought that she had a left peripheral facial palsy. The eye examination at that time was entirely normal. Five months later she returned complaining of drooping of the right eyelid, double vision and difficulty in swallowing, all increased by activity. At that time there was marked ptosis of the right lid and restriction of all extra-ocular movements. Faradic stimulation of the sternomastoid muscles gave definite myasthenic reactions.

Prostigmin 1.5 mg. and atropine sulfate 0.6 mg. were injected subcutaneously. Within five minutes the ptosis of the right lid disappeared and extra-ocular movements were well performed.

She was given ephedrine sulfate 25 mg. three times a day orally, and there was some subjective improvement. Because of a basal metabolic rate of -21 , thyroid extract 32 mg. twice a day by mouth was administered, but there was no benefit from it. Prostigmin 30 mg. three times a day orally was then tried. It helped the chewing, swallowing and double vision, but its effects wore off in from two to three hours and the patient thought that the muscle weakness was worse then than before the drug was taken. During the time prostigmin was used she developed occasional regurgitation of liquids through the nose. However, in general there was improvement in muscle strength following the use of the drug.

The final series of cases represents a group of various neurologic and muscular disorders in which prostigmin was administered. These cases are recorded in the accompanying table.

Cases in Which Prostigmin Was Administered

Name	Age	Sex	Race	Diagnosis	Prostigmin	Result
M. S.	62	♀	White	Arteriosclerosis; left hemiplegia; N. VI palsy, left	1.5 mg.	Negative
A. L.	65	♂	Negro	N. VII, VIII, IX, XI, and XII rt. palsies	1.5 mg.	Negative
H. W.	26	♂	White	Myotonic dystrophy	1.5 mg.	Negative
R. B.	32	♂	White	Myotonic dystrophy	1.5 mg.	Negative
A. C.	29	♂	White	Alternating strabismus	1.5 mg.	Negative
S. G.	50	♂	Negro	Arteriosclerosis; N. VII palsy, left; hemiplegia, rt. N. VI palsy, left	1.5 mg.	Negative
M. P.	23	♀	White	Muscular dystrophy	1.5 mg.	Negative
G. G.	60	♀	White	Progressive bulbar palsy	0.5 mg. daily for 12 days	Negative
M. K.	18	♀	White	Retrobulbar neuritis; N. III, VI palsy, rt.; multiple sclerosis	1.5 mg.	Negative
C. H.	34	♂	White	Progressive muscular atrophy	1.5 mg.	Negative
C. L.	19	♂	Negro	Acute poliomyelitis with recent paralyses	1.5 mg.	Negative
P. B.	7	♂	Negro	Pseudohypertrophic muscular dystrophy	0.5 mg. for 100 days	Negative
G. M.	40	♂	White	N. VI palsy, rt.; multiple sclerosis	1.5 mg.	Negative

The difficulty in the diagnosis of myasthenia gravis is well illustrated by the following case:

CASE 5.—G. B., a white man, aged 36, married, a farmer, in the hospital from Nov. 19, 1934, to Jan. 20, 1935, had a negative family history, and the past history was excellent. Two years before entry he awakened one morning with a severe generalized headache, giddiness and nausea. He vomited copiously, had a bowel movement, suddenly became weak, and had to be carried to bed. He vomited repeatedly during the day and remained semiconscious. He was unable to open his right eyelid and saw double. After two weeks in bed he recovered sufficiently to be up and around. After that time there was persistent diplopia and impaired extra-ocular movements. There was no increase in the disability after the onset. Physical examination showed exophthalmos and bilateral ptosis, which was more marked on the right. The eyes could not be carried laterally beyond the midline. There was marked limitation of medial and upward movement and inability to move either eye down and laterally. The motion down and medially was good. There was an internal squint of the right eye. The visual fields were normal, and the visual acuity was good. The pupillary reactions were intact. The Wassermann reaction was negative. Roentgenograms of the skull were negative. Examinations of the spinal fluid, urine and blood revealed no abnormalities. The course was afebrile. On one occasion what was regarded as a myasthenic electrical reaction was obtained, but on two subsequent attempts this finding was not confirmed. He was given aminocetic acid, from 10 to 20 Gm. daily, and ephedrine sulfate, 25 mg. three times a day. In

about one month there was improvement of the ptosis. However, a marked squint and diplopia remained. He was seen from time to time and the same eye conditions were always found. Up to the present he had been doing heavy labor and no other myasthenic symptoms or signs had ever developed. May 1, 1935, he was given subcutaneously 1.5 mg. of prostigmin and 0.6 mg. of atropine sulfate. There were no objective changes in the eye signs and no subjective improvement within thirty minutes. He was then given 1 mg. more of prostigmin and after one hour there was still no change. November 1 the test was repeated with 2 mg. of prostigmin and 0.6 mg. of atropine sulfate subcutaneously with completely negative results.

At first it was thought that the patient had a ruptured aneurysm of the circle of Willis. Later, when the myasthenic electrical reaction was obtained, the possibility of myasthenia gravis had to be considered. However, the history of sudden onset accompanied by headache, vomiting and generalized weakness, the failure of development of further myasthenic signs, the complete absence of myasthenic symptoms, and the inability to confirm the electrical reactions threw doubt on that diagnosis. The final clinical impression was that the condition was the result of a bizarre form of encephalitis or of a rupture of a congenital aneurysm of the circle of Willis. Finally, the completely negative results with prostigmin furnish additional evidence that myasthenia gravis was not the cause of the illness.

COMMENT

The diagnosis of myasthenia gravis is in many instances a difficult one. In nine cases in which there was a fairly definite clinical picture the response to the injection of prostigmin was prompt and striking. In one case of doubtful diagnosis there was no response. If myasthenia gravis was present in this case it was in a state of remission. It is possible that the action of prostigmin is effective only during a period of exacerbation. In thirteen cases of other disorders in which muscular abnormalities or cranial nerve palsies were prominent features there was no response. Although this series is small, it suggests that immediate improvement following a single dose of prostigmin occurs only in myasthenia gravis. Consequently the use of this drug seems to be a valuable diagnostic test. Walker¹ suggests that in myasthenia gravis the supply of acetylcholine at the myoneural junction is deficient and that physostigmine and by analogy prostigmin, by delaying the destruction of acetylcholine, compensates for its lack. Pritchard⁴ believes that defective innervation, whether resulting from some disability of the anterior horn cells or from impaired conduction of nerve fibers, should also be corrected by prostigmin. However, in this series this was not found to be the case.

The value of prostigmin as a therapeutic agent has not been definitely established.

The reports in the literature concerning the use of prostigmin in the treatment of myasthenia gravis are conflicting.

Laurent and Walker² have successfully treated cases with small doses of prostigmin given over long periods of time; e. g., 0.5 mg. two or three times daily given subcutaneously. Larger doses were used when more severe symptoms were present. They found that the fatigue after overexertion during the prostigmin effect tends to wear off and that small amounts of ephedrine were helpful in relieving it. No increase in the myasthenic symptoms resulted after the use of the drug in this manner over long periods of time. Wade³ Ver-

9. Laurent, L. P. E., and Walker, M. B.: Oral and Parenteral Administration of Prostigmin and Its Analogues in Myasthenia Gravis. *Lancet* 1: 1457 (June 27) 1936.

biest¹¹ and Kostakow¹² also obtained beneficial results by the daily subcutaneous administration of the drug.

Mitchell¹³ found that the treatment of patients outside the hospital by this method was unsatisfactory and that better control of symptoms was obtained by oral administration. A similar view was expressed by Minski and Stokes.¹⁴ Their ambulatory patients were treated with aminoacetic acid and ephedrine. Riven and Mason¹⁵ have limited the use of prostigmin to combating the acute and dangerous manifestations of the disease. Hyland¹⁶ states that the subcutaneous use of prostigmin is impracticable because of the temporary improvement and the method and cost of this means of administration.

The oral use of prostigmin has been found by most observers to be of distinct value. Everts⁸ treated two cases for three months, and normal activity was restored in each one. Thirty milligrams given three times daily was found to be the optimum dose. Laurent and Walker⁹ have also found that prostigmin is active orally. From 25 to 30 mg. gave a result comparable to the subcutaneous injection of 0.5 mg. They were able to obtain a supply of substance 36 of Aeschlimann and Reinert's¹⁷ series, which was given in doses of from 100 to 200 mg. daily over long periods of time with good results. Improvement was first noted from forty to fifty minutes after taking the drug. The intensity of the reaction increases to a maximum at the end of two hours. It remains maximal for from six to eight hours, after which time the effect gradually wears off. They were not able to detect any increase in the myasthenic symptoms after several months of treatment. Mitchell¹³ has treated nine cases of myasthenia gravis with prostigmin by mouth. In every case the improvement has been greater than on any previous medication, including ephedrine, aminoacetic acid and parenteral prostigmin. The average daily amount used was about 90 mg., which was given in from five to six doses. In all nine cases, potassium chloride was used as an adjuvant. In five cases it was thought to enhance the action of the prostigmin, but in the other four no difference was noted. Potassium chloride alone in doses of from 6 to 12 Gm. a day was first used by Laurent and Walther,¹⁸ who found it to be of some value. Minski and Stokes¹⁴ found it to be of no value in prolonging the effect of prostigmin and stated that its use resulted in a notable increase in toxic symptoms. Wade¹⁰ came to the same conclusions.

In 1935 Denny-Brown¹⁹ suggested the use of 20 minims (1.25 cc.) of tincture of belladonna by mouth, followed in twenty minutes by one-sixth grain (0.01 Gm.) of physostigmine salicylate in water, given once daily on an empty stomach. Hyland¹⁶ tried this in sev-

eral cases. In none was it beneficial and in four it was associated with an increase in symptoms and varying degrees of nausea.

In certain cases the use of prostigmin may be harmful. Hyland¹⁶ noted that with each succeeding injection less benefit was observed, and weakness and fatigue of muscles became progressively worse after the effect of the drug had worn off. In case 4 of the present series each succeeding dose had less effect and the patient finally died of respiratory paralysis despite frequent subcutaneous injections of the drug. Laurent and Walker⁹ state that the fatigue subsequent to the prostigmin effect eventually wears off.

In our experience the parenteral use of prostigmin has been quite helpful as a diagnostic test, and in the presence of an increase of symptoms such as frequently accompanies an infection of the upper respiratory tract. We have not attempted to treat patients by this method while they were outside the hospital.

Although the use of prostigmin by mouth is the most satisfactory treatment for these patients at the present time, the results in the present series of cases have not been as completely satisfactory as most of those previously reported. Patient 1 received the drug for eight months with striking improvement in her symptoms. However, the development of an infection of the upper respiratory tract necessitated the resumption of subcutaneous injections. Patient 8 has been taking the drug for eleven months. Definite benefit has resulted but the symptoms are so marked that even while taking 150 mg. of the drug a day he has not been able to be ambulatory. Patient 6 was greatly improved for a few weeks. Then the prostigmin lost its effect when taken orally and hypodermic injections were resumed. Patient 9 has had partial improvement over a period of two months, while patient 2 reported no decrease in the severity of his weakness after several weeks of 100 mg. daily.

Of unusual interest is case 1, in which a maculopapular rash simulating measles developed a short time before each serious exacerbation of the symptoms. A rash of similar description was noted by Rothbart²⁰ in one of his cases, but no other mention of it was found.

SUMMARY

1. The administration of prostigmin to nine patients with myasthenia gravis resulted in a striking immediate improvement in the signs and symptoms.
2. The administration of a single dose of prostigmin in fourteen cases of other neurologic and muscular disorders produced no immediate improvement.
3. Prostigmin seems to be of value in the diagnosis of myasthenia gravis.
4. The oral administration of prostigmin seems at present to be the most valuable therapeutic agent in the treatment of this disease, although some patients are not completely relieved of symptoms by its use.

The Mystery of Life.—A great deal of cant is talked about the mystery of life, as if life were somehow more mysterious than the rest of Nature. When a man says that one fact of Nature is more wonderful than another, he is at fault. The striking of a match is every bit as wonderful as the working of a brain: the union of two atoms of hydrogen and one of oxygen in a molecule of water is every bit as wonderful as the growth of a child. Nature does not class her works in order of merit; everything is just as easy to her as everything else. —Paget, Stephen: *Confessio Medici*, New York, Macmillan Company, 1931.

MORTALITY FROM CESAREAN SECTION
IN INDIANAPOLIS AND THE
CENTRAL STATES

DAVID L. SMITH, M.D.
INDIANAPOLIS

Prior to 1929 no study had been made of the results of cesarean section in Indianapolis. In order to compare local work with that in other cities, and particularly with that in the larger maternity hospitals, I made a study of cesarean section in Indianapolis for the preceding year.

The statistics from the four Indianapolis hospitals from Nov. 1, 1927 to Nov. 1, 1928 are given in table 1.

These figures were significant in several ways. In the first place, although not as bad as in some other cities, a maternal mortality of 11.3 per cent was much too high. In each group of nine cesarean sections one mother had died.

TABLE 1.—Statistics from Four Indianapolis Hospitals for One Year

Hospital	Deliveries	Section	Maternal Deaths		Fetal Deaths		Incidence
			Number	Per Cent	Number	Per Cent	
A	741	45	6	13.3	6	13.3	1:16
B	631	29	5	17.2	1	3.4	1:21
C	487	26	1	3.8	2	7.6	1:18.6
D	174	6	0	0	0	0	1:29
	2,033	106	12	11.3	9	8.7	1:19

How much too high this local maternal death rate of 11.3 per cent was is apparent in view of a report published by the Chicago Lying-in Hospital at about the same time of 731 consecutive low cervical sections with a maternal death rate of 1.2 per cent.

TABLE 2.—Indianapolis Statistics for 1934 and 1935

This study also showed that of six eclamptic patients delivered by section in Indianapolis that year two had died, a maternal mortality of 33⅓ per cent. This high mortality was in keeping with that in Detroit of 42.7 per cent, as reported by Wertz, and Peterson's¹ study of 500 eclamptic patients delivered by section with a death rate of 34.8 per cent, and also with Erdley Holland's² classic review of cesarean mortality in

1. Peterson, R.: Publication of the Department of Obstetrics of Michigan.
2. Holland, Erdley: J. Obst. & Gynaec. Brit. Emp. 28: 358, 1921.

eclamptic patients in Great Britain from 1911 to 1920, in which the maternal death rate had been 32 per cent.

The variation in maternal mortality among the four Indianapolis hospitals from 0 to 17.2 per cent and the variation in incidence of from one section in each twenty-nine deliveries to one in each sixteen deliveries was also significant.

The indications for operation as given on the hospital charts were lacking in many instances and were not convincing in many others. Also in about 95 per cent of the cases the classic technic had been used in spite of long labors, previous instrumentation and the like.

The results of this study were presented before the Indianapolis Medical Society with the hope that such a presentation and the resulting discussion would bring about a better understanding of the indications and contraindications for cesarean section as well as a substitution of a more modern technic, thereby decreasing maternal mortality in Indianapolis.

A similar study has recently been made of cesarean sections done in the same four Indianapolis hospitals for the years 1934 and 1935. The results are given in table 2.

It is apparent from these statistics that better obstetrics prevailed in Indianapolis in 1934 and 1935 than previously. A maternal mortality for cesarean section of 11.3 per cent in 1928 had fallen to 4.8 per cent in 1934 and to 3.2 per cent in 1935.

Several reasons can be given for this reduction in mortality.

First, the more widespread acceptance of the low cervical technic, the superiority of which is reflected by the 4.8 per cent maternal mortality against the 5.1 per cent mortality for the classic in 1934, and 1.8 per cent against 3.9 per cent for the classic operation in 1935.

Second, there were no sections done on convulsive eclamptic patients.

Third, I believe that the knowledge that cesarean section results were being studied each year for presentation before the local society was having a wholesome effect. General surgeons more frequently called for obstetric counsel before section was done. Also it was interesting to note from the charts that most of the sections during the years 1934 and 1935 had been done by the obstetrician instead of by the general surgeon as previously. I believe this last was responsible for the swing to the low cervical operation. However, it is

a reflection on obstetric progress in Indianapolis that the classic operation outnumbered the safer lower cervical 78 to 46 in 1934 and 102 to 54 in 1935.

The comparative safety of the classic versus the low cervical technic is accurate only when comparison is made of the results of the two as done by the same surgeon or group of surgeons. Examples of such a comparison are given in table 3.³

Commenting on Maxwell's report, De Lee⁴ says: "Again the immense superiority of the low incision is proved. How many times must it be proved before the old classical section is discarded?"

Dr. Louis E. Phaneuf⁵ reports 358 transverse cervical cesarean sections with a maternal mortality of 1.9 per cent, with only one death in the last 160 cases.

Also in answer to a letter requesting his latest figures, Dr. Joseph B. De Lee answered, Jan. 17, 1936, as follows:

We have had, from November 1914 up to date, 1,789 laparo-trachelotomies with eighteen deaths. Of these deaths, ten might possibly be ascribed to the operation. The rest are medical

TABLE 3.—Comparison of Safety of Classic versus Low Cervical Technic

	Operation		Maternal Mortality, per Cent
1. Courtiss and Fisher.....	Classic 624	7.8	
	Low cervical 376	1.3	
2. Greenhill.....	Classic 147	4.76

	Low cervical 60	0	
4. Maxwell.....	Classic 113	6.1	
	Low cervical 165	0	

deaths. During the same time, we have had 168 classic cesarean sections, with eleven deaths, of which two were ascribable to the operation. The mortalities are 1 per cent and 6.5 per cent respectively.

The Indianapolis work as reported here is considered the first phase of this work. The second phase is the report of material received in answer to 200 questionnaires sent to members of the Central Association of Obstetricians and Gynecologists. This investigation was considered worth while because it would give a reasonably accurate cross section of work done in a large area of the United States and because it represented the work of men limiting their work to obstetrics and gynecology. Also it would furnish another standard with which to compare the Indianapolis work.

Two hundred of these questionnaires were sent out. One hundred and fifty-three replies were received, all of which were filled out completely down to the question asking for statistics of the operator's own cases. Sixty-three of the 153 reported these statistics. Therefore the results as tabulated are compiled from those numbers of returned questionnaires (table 4).

The answers need no comment down to the description of the technic of uterine closure. There were so many variations in this that tabulation or summation was impossible. In the classic technic, most men closed in three layers, the last one being a peritonealizing suture. There was about an equal division between

interrupted and continuous sutures. The suture material ranged from plain number 1 catgut to twenty day chromic number 2 catgut.

In the low cervical technic most men reported a three layer closure. There was about an equal division as to the use of an interrupted or a continuous suture for the first row. Most men used a continuous suture for the second and third layers. There was a marked prefer-

Type	Total Number	Number of Maternal Deaths	Fetal Deaths
Classic	1,504	43	30
Low cervical	3,889	33	106

ence for twenty day chromic number 2 catgut with twenty day chromic number 1 next.

The figures on closure of the abdominal wall need no comment except that the sum total of answers does not total 153 in every case, because all questions were not answered on all questionnaires.

The totals of sections reported of each kind with their accompanying mortalities are given in table 5.

TABLE 5.—Central Association Statistics

Type	Number	Maternal Deaths		Fetal Deaths	
		Number	Per Cent	Number	Per Cent
Classic.....	1,504	43	2.85	30	1.99
Low cervical.....	3,889	33	0.84	106	2.72
Totals.....	5,393	76	1.40	136	2.52

These totals include ninety-seven sections done by me, of which forty-six were of the classic type with four maternal deaths and fifty-one were of the low cervical type with no maternal deaths. There were no fetal deaths. The four maternal deaths among the classic group were due to the following causes: aspiration of vomitus after completion of anesthetic with asphyxia in five minutes; general peritonitis; coronary embolus; pulmonary embolus.

SUMMARY

1. From Nov. 1, 1927, to Nov. 1, 1928, in four Indianapolis hospitals, the maternal mortality accompanying cesarean sections was 11.3 per cent.

2. In 1934 the mortality rate fell to 4.8 per cent. The rate for the classic technic was 5.1 per cent and for the low cervical it was 4.3 per cent.

3. In 1935 in the same four Indianapolis hospitals the maternal mortality decreased to 3.2 per cent, the rate for the classic operation being 3.9 per cent, while that for the low cervical was 1.8 per cent.

4. Data have been presented representing the cesarean section practice, preference and technic of 153 members of the Central States Association of Obstetricians and Gynecologists.

5. Sixty-three of these members reported 5,393 cesarean sections with a maternal mortality of 1.4 per cent and a fetal mortality of 2.52 per cent.

6. Of these 5,393 operations, 1,504 were classic cesarean sections with a maternal mortality of 2.85 per cent, and 3,889 were low cervical cesarean sections with a maternal mortality of 0.84 per cent.

7. It is apparent from a study of the Indianapolis work and that reported by the members of the Central States Association of Obstetricians and Gynecologists that the low cervical section is the operation of choice.

THE ANTIGENIC PROPERTIES OF INSULIN

JULIAN H. LEWIS, PH.D., M.D.
CHICAGO

The establishment of insulin as a complete and soluble protein¹ anticipated its property as an antigen. The allergic reactions that are often associated with its clinical use indicate that it is active in this respect. The greater prevalence of hypersensitivity to insulin preparations when they first began to be generally used as compared to substances now in use is probably to be attributed to the presence of extraneous substances that have for the most part been eliminated with the development of better processes of manufacture. Nevertheless reactions, both general and local, do still occur with the refined substances and present a baffling problem in the treatment of diabetes.

Commercial preparations of insulin are derived from either beef or pork tissues or indiscriminately from both. Studies of cases of hypersensitivity to insulin show that most of them are sensitive to the insulin protein itself, although some show sensitization to the protein of the species from which the insulin was prepared. Aside from their chemical importance these studies are of significance because of their bearing on the specificity of the insulin protein. The type of specificity of a given protein of animal origin is designated, first, by its immunologic relationship to other proteins of the same species and, secondly, by its immunologic relationship to the same protein of other species.

Barral and Roux² found that guinea-pigs sensitized with a saline extract of beef pancreas or with beef

serum did not give anaphylactic reactions with commercial preparations of insulin; nor did insulin sensitized animals react with beef pancreas or with beef serum, although they did react with insulin. They concluded from these experiments that insulin was devoid of either organ or species specificity.

The present report includes a repetition of these experiments under more precise conditions, as well as additional ones planned to find the immunologic relationship of two insulins derived from different species of animals. The preparations used were beef insulin and pork insulin. While neither was actually crystalline material, they were "practically as pure as crystalline insulin."³ Their activity is 20 units per milligram.

Virgin female guinea-pigs were sensitized with 1 mg. each of either of the two insulins, which was injected subcutaneously either in one single dose or in divided doses given over a period of twenty-four hours. The hypoglycemia that resulted was effectively controlled by administering a solution of dextrose by mouth before the injections were made and, at necessary intervals, subcutaneously and intraperitoneally. After a suitable incubation period the uteri of these animals were tested for anaphylactic sensitization with the Schultz-Dale technic.

REACTION OF UTERI SENSITIZED WITH BEEF INSULIN TO EXTRACTS OF BEEF PANCREAS, TO BEEF SERUM AND TO BEEF INSULIN

The extract of beef pancreas was made by grinding the fresh gland with saline solution in a mortar containing sand. The mixture was centrifugated and the supernatant fluid heated to 56 C. for one-half hour. The beef serum was similarly inactivated. Solutions of the insulins were prepared by dissolving them in a small amount of weak alkali, which was rapidly diluted with saline solution. The solutions were then adjusted as nearly as possible to a neutral reaction by adding dilute acid.

Uteri of guinea-pigs sensitized to beef insulin and suspended in the chamber of the Dale apparatus were exposed in turn to the extract of beef pancreas, beef serum and beef insulin. Chart 1 illustrates the type of reactions consistently obtained in this series of experiments. The tracings show that uteri sensitized with purified beef insulin reacted when exposed to this substance but did not react in the presence of beef pancreas protein or beef serum. These experiments indicate, like those of Barral and Roux, that the insulin protein, although obtained from the pancreas, was distinct from the bulk of the protein from this gland. An extract of pancreas must undoubtedly contain insulin protein but probably in such comparatively small quantities that its presence is not detectable with uteri sensitized to the insulin protein. The absence of reaction with beef serum, which is a strongly species specific antigen, shows that insulin is not species specific.

CROSS REACTIONS BETWEEN BEEF INSULIN AND PORK INSULIN

Virgin female guinea-pigs were sensitized with 1 mg. of beef insulin or with the same quantity of pork insulin. The uteri of these animals were tested for sensitization, first with the heterologous insulin and then with the homologous one. In each case there was an active contraction when the uterine strip was exposed to the insulin not used for sensitization. But

From the Otho S. A. Sprague Memorial Institute and the Department of Pathology, University of Chicago.

1. A review of the chemistry of insulin is given by Jensen, H.: *Science* 75: 614 (June 10) 1932.

2. Barral, P., and Roux, J.: *Compt. rend. Soc. de biol.* 106: 292 (Feb. 6) 1931.

3. These preparations were obtained from Eli Lilly & Co. by the courtesy of Dr. George H. A. Clowes, who verifies for their purity.

when complete desensitization was obtained to the heterologous protein there was still demonstrable in most instances a small amount of sensitization to the homologous protein. Typical of these experiments are the tracings shown in chart 2. There is, apparently, an antigenic activity in common between the two insulins, but there is also a residuum of specificity inherent to the species. It would appear that the chemical and immunologic properties of insulins are very closely related although, from these experiments, they are not completely identical.

These experimental facts are corroborated by certain clinical observations, although others do not bear them out. Tuft,⁴ who reviews the literature on insulin hypersensitization reported prior to the publication of his article in 1928, cites a case in which severe generalized urticaria and marked subjective symptoms developed following injections of insulin, although previous daily injections over a period of a month or two gave no such reactions. Insulin had to be discontinued and the patient placed on a maintenance nonglycosuric diet. Skin tests made with commercial preparations of insulin from both pork and beef pancreas gave severe reactions, as also did purified recrystallized insulin protein (animal source not given). However, extracts of beef and pork meats gave no reactions. The patient's serum could convey the same type of sensitization to normal skin with the use of the Prausnitz-Küstner technic. Precipitins for crystallized insulin could be demonstrated in the patient's serum ten days after a generalized reaction, although complement fixing and anaphylactic sensitizing antibodies could not be detected. The precipitins disappeared by the fifth week after the reaction and the skin sensitizing properties of the serum disappeared by the fourth month, although the skin sensitivity of the patient was still present at that time. Grishaw⁵ reports an instance of a patient who had local and general reactions with insulin from pork and also from beef, the two supplied by the same manufacturer. Another preparation from beef obtained from a second manufacturer also gave reac-

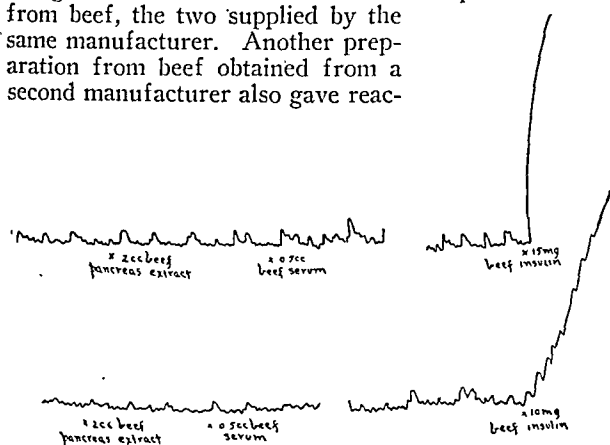

Chart 1.—Uterine tracings of guinea-pigs sensitized with 1 mg. of beef insulin.

tions, although a preparation from a third manufacturer, also obtained from beef, gave no reaction. Acetone, which precipitated the proteins and made the insulin inactive, removed the skin-reacting agent from the filtrate. Campbell, Gardiner and Scott⁶ found that patients sensitive to commercial preparations of beef insulin are also sensitive to crystallized beef insulin.

The question has been raised whether insulins from different species are similar. Tuft⁴ believes that it is another substance of immunologic specificity, since it has been shown that distinct hypersensitiveness to insulin protein irrespective of its biologic source can be present, whereas no sensitivity to the proteins of other tissues of the same animal could be demonstrated. In this respect insulin is similar to the lens protein, casein and the brain antigen. These facts are further in

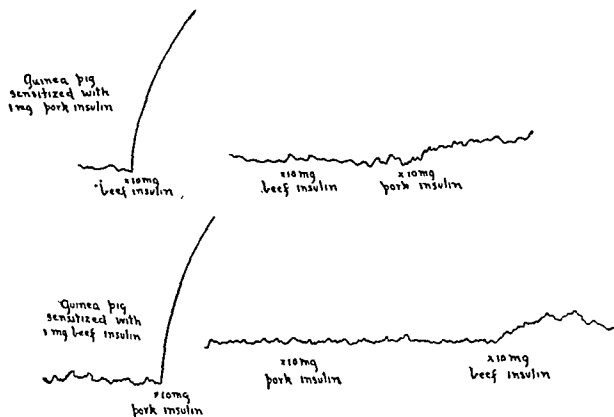

Chart 2.—Uterine tracings of guinea-pigs sensitized with insulin.

accordance with the statement of Wells⁷ that substances of the body with a definite action and a product of cell activity with a given function to perform which is alike in all species, such as trypsin, epinephrine, thyroxine and insulin, should be similar for all species in contrast to the blood and tissue proteins, which have to do with the general metabolism of the species from which they come. Furthermore, chemical analyses of insulin crystals from various sources show a very close similarity in composition and structure. Scott,⁸ however, points out certain discrepancies in the acceptance of the identity of all insulins. In the first place, Dingemans⁹ reports the production of a more powerful but amorphous insulin by adsorption and elution of the insulin, charcoal being used as the adsorbent, although these experiments have not been confirmed by other workers.¹⁰ Secondly, Jensen and his co-workers¹¹ have reported a difference in the sulfur content of hog and beef crystallized insulin, but they admit that the difference may be due to impurities in the hog insulin. He finally points out the reports of patients sensitive to beef insulin who can be given hog insulin without reaction, and vice versa. It is probable that these cases were instances of sensitivity to contaminating proteins rather than to the insulin. Williams¹² reports two such cases showing gastro-intestinal symptoms when hog insulin was given but not reacting when beef insulin was given. Skin tests made with hog protein were positive but with beef protein were negative. Scott, however, does not bear out his criticisms in a comparison of crystalline insulins from the pancreas of ox, hog, sheep and fish. He found that the crystals from all sources had a similar microscopic appearance. Their solubility and iso-electric

points appeared to be identical. There was a remarkable agreement in the unitage per milligram of solids. The results of chemical analyses for carbon, hydrogen, nitrogen and sulfur show a very close agreement with one another.

Bryce¹³ tested a patient sensitive to insulin with three kinds of insulin, those from pork, beef and sheep, and found that they gave the same kind and size of local reactions. Extracts of pork and beef muscle gave no reactions. Hajek¹⁴ discovered a patient who gave reactions to a commercial preparation of insulin that was apparently made from both beef and pork glands. When an insulin made from beef glands alone was given, no reaction followed. Neither were reactions obtained with extracts of muscle from mutton, lamb, pork, horse, goat and lobster. Karr, Kreidler, Scull and Petty,¹⁵ in studying a case of insulin hypersensitivity, found that the subject they reported gave skin reactions to pork and beef insulins and to a crystalline insulin whose source is not given. The serum of the patient gave a precipitin reaction with an insulin, the type of which is also not mentioned. When this serum is mixed with insulin, the activity of the latter is not affected. A rabbit immunized with insulin produced a precipitating serum but only when the insulin used for immunization was injected, mixed with the patient's serum. Allan and Scherer¹⁶ found during a period of about four years 161 cases of insulin hypersensitivity among 1,907 diabetic patients treated at the Mayo Clinic. Of these, 100 cases were studied as to the control of their reactions. In some instances reactions disappeared when the type of insulin was changed and in others they persisted when insulin of any source was used. The authors believe that in the former case the sensitivity was to contaminating proteins while in the latter the sensitivity was to the insulin protein. However, the patients thought to be sensitive to contaminating proteins did not react to other proteins, such as those of muscle derived from the same animal that provided the insulin. Although a patient may be sensitive to all types of insulin, owing to the presence of a hormonal characteristic protein, the authors believe that the human insulin protein is different from all other types, since they cannot conceive of a patient being sensitive to his own insulin.

Davidson¹⁷ reports a case of diabetes in which a severe urticaria developed whenever insulin of any type, including pork insulin and crystallized insulin, was administered. Sammis¹⁸ cites an instance of severe reaction in a nondiabetic patient given insulin because of underweight. Further tests showed the patient to be equally sensitive to beef insulin, sheep insulin and "synthetic" insulin.

If all insulins are chemically and therefore immunologically identical, the same question of iso-antigenicity arises as with other antigens of similar properties, such as lens protein, casein, brain, fibrinogen and thyroglobulin. If insulin from one species is identical with that of another species, a given animal should be able to form antibodies when injected with insulin from any and all sources, including that from the species of animal injected. This iso-antigenicity has been proved

for all antigens for which there has been demonstrated a nonspecies specificity.¹⁹ Similar experiments with insulin would in all probability give the same results. However, as with fibrinogen and thyroglobulin, a paradoxical situation is encountered in that insulin, in all probability an iso-antigenic substance like these other two proteins, occurs in the circulating blood, which is the condition *par excellence* for the formation of antibodies when ordinary antigens are used under experimental conditions. Yet, as with fibrinogen and thyroglobulin, there is no evidence that antibodies are formed under normal conditions.

Another striking and unexplained fact becomes evident and is discussed in a previous paper on the iso-antigenic properties of casein.¹⁹ There are many thousands of people who receive daily injections of insulin preparations containing a protein capable of stimulating the formation of antibodies. Experimental animals receiving an antigenic protein under similar circumstances develop a high degree of sensitization, as manifested by severe local reactions as well as by general manifestations. Yet of all the people who are treated with insulin, even over long periods of time, only a comparatively few develop sensitization. There seems to be some other condition necessary than the parenteral introduction of antigen alone for the development of sensitization in man which is not necessary in lower animals. The mechanism that ordinarily protects a person from the dire results of repeated administration of an antigen appears to break down in allergic states. It is of interest to note that in a number of the cases of insulin hypersensitization this condition was present at the very first injection of insulin.

One may imagine that this failure of a protective mechanism which operates against the development of iso-antigenic activity might result in hypo-insulinism, deficiency of fibrinogen, the various disturbances of thyroid function, and mental diseases, as an expression of allergy to the corresponding iso-antigenic substances.

SUMMARY

1. Insulin protein is an active antigen.
2. Since insulin protein does not react in common with pancreas protein, its specificity is independent of that of the major constituents of the pancreas.
3. Insulin protein is without species specificity, since it has no antigenic activity in common with other proteins of the same species and which are strongly species specific.
4. Insulin proteins from different animal sources are immunologically closely related.

Clinical Notes, Suggestions and New Instruments

SUCCESSFUL TREATMENT OF TWO CASES OF FAMILIAL PERIODIC PARALYSIS WITH POTASSIUM CITRATE

MARVIN S. HERRINGTON, M.D., DURHAM, N. C.

Familial periodic paralysis is a rare disease characterized by abrupt attacks of flaccid paralysis, without sensory loss or psychic disturbances of any sort, and from which recovery is complete. In about 80 per cent of cases the disease is hereditary. It is transmitted by both sexes, but males are affected twice as frequently as females. The etiology of the disease is unknown and postmortem examinations and biopsies have thrown no light on the condition.

The attacks may begin in childhood, but more often at puberty, and may be delayed until the age of 20 or 21. The onset is usually in the early morning and not uncommonly the patient awakes partially paralyzed, and complete paralysis develops. The muscles of the limbs are chiefly affected, the paralysis being as a rule symmetrical, but monoplegias and hemiplegias have been observed. The muscles concerned with speech, vision and deglutition usually escape, but the abdominal muscles are affected and, in severe cases, the respiratory muscles may become so weak that phonation, coughing and sneezing are impossible. The electrical excitability of the affected muscles to all currents is completely lost. Sphincter function is unimpaired, but retention of urine and feces during an attack is the rule. The reflexes are lost in the affected muscles.

The paralysis lasts from a few hours to three or four days, or even longer, and the attacks vary greatly in frequency, occurring every few days or separated by intervals of months or years. Schoenthal,¹ Singer and Goodbody,² Gardner³ and Holtzapple⁴ have given detailed descriptions and reviews of the literature.

The obscurity of the etiology of the disease is reflected in the variety of treatments that have been employed. This brief report details the apparently successful treatment of two brothers, suffering from familial periodic paralysis, with potassium citrate, a form of treatment which has been used before in this disease.⁵

The family history of the two brothers reveals that one maternal uncle and one female cousin suffered from attacks of periodic paralysis. The uncle died during an attack at the age of 35. The cousin is living at the age of 40 and is well except for an occasional minor attack of paralysis. Three siblings have never shown any symptoms whatever of periodic paralysis.

The past histories of both patients were completely noncontributory, and physical examinations revealed no evidence of organic disease.

CASE 1.—M. S., a man, aged 28, unmarried, a university student, began at the age of 14 to have attacks of weakness and slight paralysis of the extremities every few weeks. These attacks ceased during the summer only to return in the fall. At the age of 16 he began to suffer from paralytic attacks of greater severity, involving the trunk and all extremities. These major attacks of flaccid paralysis occurred at intervals of from one to three months. In between them he had many minor attacks, characterized by weakness of one arm or leg, which lasted for only a few hours. During the year before he began treatment with potassium citrate he was admitted to the hospital four times for attacks of major severity, lasting about two days. The minor and major attacks together seriously impaired his university work.

When examined three years ago, during an attack, all the muscles of the trunk, arms and legs were in a state of flaccid paralysis, with total areflexia. The examination was otherwise quite negative.

In June 1934 he began to take 5 Gm. of potassium citrate when the prodromal sensations of weakness and soreness of the muscles gave warning of an impending attack of paralysis. One dose of 5 Gm. would usually abort the attack but, if it progressed, he took 5 Gm. doses every hour until he felt strong again. Under this treatment no attack has progressed to complete paralysis, usually ceasing after a short period of weakness. During the past year he has not lost a single hour from his work as a student.

CASE 2.—E. S., a man, aged 31, a mechanic, brother of M. S., began at the age of 16 to have attacks of moderate weakness of the extremities and a few months later suffered from a major attack, with complete flaccid paralysis lasting forty-eight hours. He continued to have minor attacks, lasting a few hours, except during the summer, and then one year after the first major attack he had a second seizure, with complete paralysis of the muscles of the trunk and extremities. Since the age of 17 he has suffered severely from periodic paralysis, at times averaging a loss of two days a week from work. At one time he had a major attack, with complete paralysis, weekly for thirteen successive weeks.

In 1934 he began to take potassium citrate in 5 Gm. doses at the first sign of an attack, repeating the dose hourly if needed, and during the past two years he has been able to pursue his work as a mechanic without serious interruption. Now and then he suffers a few hours of muscle soreness and weakness, but these symptoms never proceed to complete paralysis as they did before he began treatment with potassium citrate.

The attacks of periodic paralysis are so irregular in their occurrence that neither brother has attempted to use potassium citrate prophylactically; they commence treatment only with the appearance of prodromal symptoms. Sodium citrate is totally ineffective in treating the attacks. The younger brother has used as much as 25 Gm. of potassium citrate in the space of six hours without harmful effect. Occasionally mild catharsis follows the use of several 5 Gm. doses.

SUMMARY

Potassium citrate has controlled the attacks of familial periodic paralysis in two brothers so well during the past two years that both have been restored to economic efficiency.

A NEW METHOD FOR OPENING A CARBUNCLE

CHARLES B. MABRY, M.D., JACKSONVILLE, FLA.

Not long ago I had a series of carbuncles, furuncles or old fashioned boils. Pain forcefully moved in and occupied my attention. A means of combat was sought and one finally found which was so successful that I have been asked to make this relief known.

For many ages the primary reason for a large number of patients consulting a physician has been to seek relief from some form of pain. Much has been written and much more will be written on and because of pain. Its degree, its duration, its intensity, its location and its character have had and will continue to have marked effect on human behavior individually and collectively. In recent years new forms of anesthesia have been produced and many painful procedures have been robbed of their former agony.

A furuncle hurts. It hurts because the tension caused by forces combating the infection together with the infection form a firm, hard mass which presses on hypersensitive nerves. The slightest pressure on this indurated mass causes an alarming pain.

For a long time physicians have been deceiving themselves and their patients by freezing the furuncle with ethyl chloride before incising. We all know how little anesthesia has been accomplished, because the skin only has been anesthetized. It is impossible for the freezing to reach the depths of the indurated mass and anesthetize these deep indurated hypersensitive nerves, because the anesthesia is only a few millimeters deep. The freezing has made the skin tough to cut, so that it has been necessary to use additional pressure on the knife to make an

ample incision. The furuncle having been opened, the patient screams, turns pale, breaks out in a cold perspiration and then faints or vomits or both.

A new method which in my hands has been successful in making this hitherto agonizing procedure almost painless consists of only one new step. The furuncle is frozen as has always been done. A towel clamp now grasps the frozen skin and lifts it up or away from the body while the knife makes pressure

Method of incising a furuncle without causing pain.

inward. The inward pressure of the knife becomes a balancing or counteractive force against the towel hook. This prevents the deep pressure being made over the hard, inflamed hypersensitive mass and eliminates the pain, because the pain has always been caused by the knife pressure on the indurated mass and not by the cutting.

It is astonishing how little the patient is hurt. The furuncle having been drained, a dressing is applied in the usual manner.

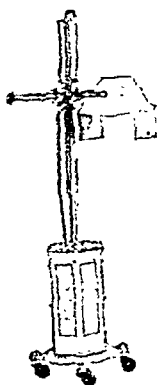

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT. HOWARD A. CARTER, Secretary.

BURDICK LA-440 ULTRAVIOLET LAMP ACCEPTABLE

Manufacturer: The Burdick Corporation, Milton, Wis.

The Burdick LA-440 Ultraviolet Lamp is a high intensity quartz ultraviolet lamp for professional use. The burner, Uviarc Mercury Quartz type, is similar in construction to the burners used in other Burdick Ultraviolet Lamps. The electrodes are sealed in by graded fused seals. The burner does not need to be tilted when starting, but merely shaken slightly. It is available for either alternating or direct current. When operating on alternating current, it is self rectifying.

Burdick LA-440 Ultraviolet Lamp.

The reflector is chromium plated and designed to distribute radiation over a treatment area approximately 2 by 6 feet at a distance of 3 feet. The reflector rotates and is adjustable to any position from horizontal to vertical.

The adjustable, counterbalanced 6 foot stand has a 30 inch vertical adjustment and a cross arm having a 25 inch extension with 10 inch adjustment. Moving parts have ball bearings.

The control unit is housed in a hexagonal metal cabinet and includes a meter indicating when the lamp is operating at full intensity. The unit is mounted on 3 inch solid rubber, ball bearing casters.

The ultraviolet radiation generated by this lamp is of a sufficient intensity to produce a first degree erythema on the average skin in a minute and a half at a distance of 30 inches.

The operating characteristics are as follows:

Alternating Current	Direct Current
Line voltage 105-125	Line voltage 105-125
Starting amperage on line 8.0	Starting amperage 6.6
Operating amperage on line 5.0	Operating amperage 3
Normal burner voltage across anodes 164	Maximum burner voltage 72
Operating watts from line 400	Starting burner voltage 15
Cathode burner operating amperage 4.6	
Maximum burner equivalent voltage 50	
Starting burner voltage 18	

The Burdick LA-440 Ultraviolet Lamp has the same burner and reflector as the Burdick Anniversary Model Ultraviolet Lamp, which was accepted by the Council (THE JOURNAL, Dec. 9, 1933, p. 1879). The difference lies in (a) the stand and control, the LA-440 having a 6 foot counterbalanced stand with a 30 inch vertical adjustment and a 25 inch cross arm with 10 inch adjustment; (b) a larger control cabinet, equipped with a meter to indicate when the lamp is at full intensity.

This lamp was investigated in a clinic acceptable to the Council for a period of three months. It was found to be satisfactory for the application of ultraviolet rays in clinical practice.

In view of the foregoing report, the Council voted to include the Burdick LA-440 Ultraviolet Lamp in its list of accepted devices.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS. PAUL NICHOLAS LEECH, Secretary.

"SULFANILAMIDE" (THE COUNCIL NAME FOR PARA-AMINO BENZENE-SULFONAMIDE)

A number of pharmaceutical firms have submitted to the Council preparations of para-aminobenzenesulfonamide, which is not protected by patents. Among the proprietary names under which the product is marketed are Prontylin, Stramid, Streptocide, Colsulanyde and Prontosil Album. The Council on Pharmacy and Chemistry has not completed its consideration of para-aminobenzenesulfonamide and therefore has not issued any statement concerning the acceptability or nonacceptability of the product for inclusion in New and Nonofficial Remedies. However, considerable correspondence has been carried on between the Council and several firms with reference to a nonproprietary term for the preparation. One firm suggested the name "Sulfanilamide." Although the Council preferred a shorter term, a representative of this firm, which was the first to submit a nonproprietary product to the Council, pointed out that "Sulfanilamide" denoted the composition and that the name was being used abroad at the present time. Other interested concerns agree to the term. The Council has therefore formally adopted the nonproprietary name "Sulfanilamide" for para-aminobenzenesulfonamide.

RIBOFLAVIN, THE ACCEPTED NAME FOR VITAMIN B₂

Recently there has been submitted to the Council by Hoffmann-La Roche, Inc., a preparation termed Lactoflavin (Synthetic) "Roche." While this product was under consideration by the Council a communication was received from the chairman of the Committee on Vitamin Standards of the American Society of Biological Chemists in which occurred the following statements:

"There seems to be a fairly general agreement among investigators in the field of vitamins who have discussed this question of nomenclature that the name 'flavin' should be given to a water-soluble pigment that has been demonstrated to be necessary for the normal nutrition of the rat and for growing chicks (Lepkowsky and Jukes: *J. Biol. Chem.* 111:119, 1935. Chick, Copping and Edgar: *Biochem. J.* 29:721. György, Paul, *ibid.* 29:741, 1935).

"Dr. H. C. Sherman has used the term 'vitamin G' for this substance and a number of continental European workers have used the term 'vitamin B₂', which was first suggested by Kuhn. English investigators use the term 'flavin.' At a conference of a group interested in this question of nomenclature during the session of the recent American Chemical Society meeting at Pittsburgh, the opinion was unanimous that the term 'flavin' should be used to designate this pigment and that the terms 'lactoflavin,' vitamin G, and 'vitamin B₂' should not be used. I am opposed to the use of the term 'lactoflavin' for a synthetic preparation, which obviously does not come from milk and which appears to have been first isolated from egg white. Ellinger and Koschura (*Ber.* 66:315, 1933) reported in 1933 the isolation from whey of a substance which they called 'lyochrome' having the empirical formula $C_{35}H_{33}N_{32}$. Kuhn, György and Wagner-Jauregg (*Ber.* 66:317, 1933) reported a few days later the isolation of a substance 'Ovoflavin' from egg white; but they proposed no formula. A short time later (*Ber.* 66:576, 1933) the same authors proposed a formula $C_{17}H_{20}N_4O_6$ for this substance, reported decomp. point 265° and also stated that the absorption curve of the substance in water showed maxima at 360 and 440 mμ. Ellinger and Koschura (*Ber.* 66:808, 1933) then reported the isolation of a substance which they called lactoflavin from whey having the empirical formula $C_{10}H_{18}O_{12}N_{14}$. Shortly thereafter Kuhn and his co-workers (*Ber.* 66:1034) reported the isolation of a lactoflavin from milk having the same empirical formula as their previously isolated ovoflavin, melting with decomposition at 267°, and having an absorption curve 'extraordinarily similar' to ovoflavin. The structural formula of naturally occurring flavins has now been established beyond question and the empirical formula is in agreement with that assigned to ovoflavin by Kuhn. It appears therefore that a flavin was first isolated from egg white. Synthetic flavin, which was first prepared by Karrer (*Helv. chim. acta* 17:1010, 1934) and Kuhn, Reinemund and Weygand (*Ber.* 67:1460, 1934), has been shown to be chemically identical with flavin isolated from milk and to have the same biologic value for rats by von Euler, Karrer, Malmberg, Schopp, Benz, Becker and Frei (*Helv. chim. acta* 18:522, 1935), who used the term "riboflavin."

"In assigning the name to the lactoflavin of Hoffmann-LaRoche, Inc., consideration must be given therefore not only to a suitable name for a commercial product but also the name of what is now recognized as being a chemically pure vitamin. The name should therefore be in as good agreement with current vitamin nomenclature as is practicable."

The Council's referee in charge of this product considered this communication and made the following comments:

"As to the suggestions of the chairman of the Committee on Vitamin Standards of the American Society of Biological Chemists, I agree that it would probably be desirable to omit the prefix 'lacto.' Personally, I would much prefer to get away from the implication that the compound is derived from a single source. As has been pointed out, the product was first isolated from egg white. The evidence is rather convincing that the flavins obtained from egg white, milk, liver, pancreas and a number of other sources are identical in structure and manifest the properties of vitamin B₂.

"It should be noted that the term flavin is used in the literature for a variety of synthetic products of similar structure, many of which manifest little or no vitamin activity. As far as I have been able to determine, any compound which contains the isalloxazine nucleus is referred to in the literature as a flavin. Indeed, the term flavins represents a class of compounds, just as do the terms alcohols, ethers, alkaloids, etc. If 'flavin' without a prefix is preferred, perhaps the meaning could be safeguarded by stating that the term applies to the naturally occurring flavin, having the formula $C_{17}H_{20}N_4O_6$, and manifesting the physiological activity hitherto ascribed to vitamin B₂ or G. However, since flavin is a class name, I would prefer a suitable prefix. It seems to me that the compound might be referred to as d-Riboflavin or just Riboflavin. This would indicate that the compound hitherto denoted as vitamin B₂ is a ribose derivative of isalloxazine. This would prevent confusion with many synthetic products also called flavins but which are devoid of ribose."

On recommendation of the Committee on Nomenclature, the Council concurred in these recommendations and voted that the product described as "6,7-dimethyl-9-d,1'-ribityl-isoalloxazin" shall be known as "Riboflavin," so far as products which come under the consideration of the Council are concerned.

The Council has not completed its consideration of Riboflavin "Roche" with a view of acceptance; when it is completed, the description of the product will appear in THE JOURNAL.

Council on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION, TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

FRANKLIN C. BING, Secretary.

HOOR GLASS BRAND TABLE SALT IODIZED

Manufacturer.—The Barton Salt Company, Hutchinson, Kan.

Description.—Table salt containing magnesium carbonate (1.0 per cent) as a caking inhibitor and potassium iodide (0.02 per cent).

Manufacture.—The salt brine, obtained by returning the water forced into the salt veins by means of drilled wells, is settled to remove turbidity, treated with lime and soda ash to remove the calcium and phosphates, and evaporated. The salt is washed, dried and screened. The magnesium carbonate and potassium iodide are added and the salt is packed in cartons.

Analysis (submitted by manufacturer).—Moisture 0.1%, matters insoluble in water 0.02%, calcium sulfate 0.39%, calcium chloride ($CaCl_2$) 0.02%, magnesium sulfate ($MgSO_4$) nil, magnesium chloride ($MgCl_2$) 0.03%, iron and aluminum oxides nil, sodium sulfate (Na_2SO_4) nil, sodium chloride ($NaCl$) 99.43 and potassium iodide (KI) 0.02%.

Claims of Manufacturer.—For all table and cooking uses. The iodine in the salt aids in preventing simple goiter caused by insufficient iodine in the diet.

(1) SEXTON BRAND GREEN BEANS, WATER PACKED

(2) SEXTON BRAND GOLDEN WAX BEANS, WATER PACKED

Manufacturer.—John Sexton & Company, Chicago.

Description.—(1) Canned green beans, packed in water. (2) Canned wax beans, packed in water.

Manufacture.—Green or wax beans are mechanically graded for size, hand sorted, washed, blanched, again washed and hand filled into cans. The cans are filled with hot water, sealed and heat processed.

Analyses (submitted by manufacturer).—(Analyses of entire contents including liquid): moisture 95.1%, total solids 4.9%, ash 0.41%, fat (ether extract) 0.7%, protein (N × 6.25) 1.0%, crude fiber 0.51%, carbohydrates other than crude fiber (by difference) 2.3%.

Calories.—0.19 per gram; 5 per ounce.

Claims of Manufacturer.—Choice quality beans packed in water without added sugar or salt. For use in special diets in which sugar or salt is proscribed or in quantitative diets of calculated composition.

RED AND WHITE BRAND FLOUR

Distributor.—Slocum Bergren & Wash Company, Minneapolis.

Manufacturer.—Blair Milling Company, Atchison, Kan.

Description.—A hard winter wheat "long patent" flour; bleached. The same as Blair's Certified Northern Type Flour (Bleached) (THE JOURNAL, Aug. 26, 1933, p. 675).

SATURDAY, APRIL 17, 1937

GRADUATE TRAINING FOR PHYSICIANS

The education of a physician is not completed in the four years of the undergraduate curriculum. His development is a lifelong process, associated with unremitting toil and assiduous devotion to the most exacting of professions. As the frontiers of human knowledge advance, the slow and laborious progress of the pathfinder is superseded by modern means of advancement. When science displaces speculation, personal trial and error become too costly. In medicine the dissemination of new knowledge is as important as its acquisition. Our rapidly growing understanding of disease demands of the practitioner today a deeper knowledge than was available even a generation ago. Medical education has come to include graduate as well as undergraduate instruction. Examining boards in the medical specialties are requiring more fundamental and more comprehensive training of those who would be recognized as especially qualified in their several fields.

The situation, obviously, is more complicated than in undergraduate education, for the objectives and methods of graduate instruction in medicine are many and diverse. On the one hand are those who desire to fit themselves for the practice of specialties and, on the other, the large group of physicians already in practice who want to keep abreast of the latest advances in medicine. For the first group there must be provided systematic instruction in the specialties and the closely related medical sciences, as well as practical experience in the form of apprenticeships. Such apprenticeships nowadays are usually institutional rather than individual. The correlation and integration of these various types of experience is the practical problem that now confronts medical educators.

For the physician in practice, two main types of instruction must be provided: the systematic courses of the so-called postgraduate type, which can be offered only in the large cities where abundant clinical facilities are available, and the briefer programs of the university extension type, which are brought to the practitioner in his own or some nearby town. These do not

involve any serious interruption of his work. Instruction of this character has been carried on successfully by a number of state societies, sometimes with the assistance of a university faculty or with support from one of the foundations.

An important difference in the economic status of the man just graduated and the physician who has been for a number of years in practice necessitates for each a widely different type of curriculum. The aspiring specialist who has just completed his internship frequently has no capital except his education. Often he is encumbered with financial obligations. For his further education he cannot pay in cash; he must pay in services. This he can easily do, for his time is not yet very valuable. Hence apprenticeships in which the student receives instruction and maintenance in return for his services as a resident or assistant are being developed. The physician who has built up a practice, however, has an economic value which does not permit him to spend long years in service in order to obtain the instruction which he needs but does permit him to pay reasonably for what he wants. His program must be systematically and intensively arranged so as to permit his speedy return to his own community.

The American Medical Association has published much information concerning opportunities for graduate training in medicine, but the rapidly increasing importance of this phase of education now makes necessary a more comprehensive investigation. Experience has shown that personal visits as well as official reports are needed in order to present a true picture of the activities of an educational institution. The Council on Medical Education and Hospitals, therefore, is now undertaking a survey of existing facilities for graduate study and advanced training in medicine. In this way it will be able to present to prospective students, to examining boards and to special societies reliable information concerning graduate medical education.

ACUTE BONE ATROPHY

In 1900 Sudeck¹ described acute bone atrophy developing in the course of a few weeks at the site of an injury or an inflammatory process or at a distance from it and presenting in a roentgenogram a characteristic picture of a patchy bone atrophy. This is accompanied by a rapid wasting of muscles and a corresponding weakness. In cases that arise on the basis of an inflammatory process, various vasomotor and trophic disturbances are to be observed. These include cyanosis, cold and clammy skin, desquamation, atrophy of skin and subcutaneous tissues and delayed healing of wounds. Shrinking of the joint capsule may occur and lead to ankylosis. This condition is not to be confused with atrophy of inactivity; it may indeed develop in a functioning extremity.

1. Sudeck, Paul: *Deutsche med. Wchnschr.* 28: 170 (April 3) 1902; *Die trophische Extremitätenstörung durch periphere Reize*, *Deutsche Ztschr. f. Chir.* 224: 596 (Oct.) 1931.

The pathogenesis of acute bone atrophy is to be seen in the irritating stimuli proceeding from the inflammatory focus as well as in reflex trophic processes. The acute bone atrophy was observed as a complication of a variety of acute and chronic inflammatory diseases of the bones, joints and tendons as well as in fractures, dislocations, contusions, chilblains and burns. In exceptional instances the dystrophic symptom complex may persist as an independent vasomotor disease after the original lesion has healed. Sudeck distinguishes three types of the condition: peripheral, caused by external irritation; neurogenic, caused by injury to the peripheral neuron, and the thrombophlebitic. The essential feature common to all three is the disturbed circulation with consequent impairment of tissue nutrition.

In his histologic studies of sixteen clinical cases of acute bone atrophy and in his animal experiments, Rieder² observed definite signs of a beginning bone absorption before the roentgenogram could reveal them. At this stage there was pronounced hyperemia of the blood vessels of the bone. Bone destruction was characterized by the presence of narrow spindle-shaped osteoclasts. The process of ossification was retarded. The narrowing of the trabeculae, the crowding of the lamellae and the calcium deprivation spoke for inadequate bone formation—bone dystrophy. Bone atrophy resulting from inactivity does not exhibit vasomotor or trophic disturbances. Rieder found that diminished blood supply does not play a part in the production of acute bone atrophy. Ligation of the nutritive arteries of the bone and of the arterial blood supply to the extremity did not affect the bony structure. Determination of the alkali reserve after the method of van Slyke revealed no constant alteration in carbon dioxide or lactic acid content of the venous blood. Determinations of blood calcium in the blood draining the area of artificially induced acute bone atrophy revealed a diminution. The rich sympathetic nerve fiber supply of the bony framework suggests the dominant rôle of the vasomotor system in the so-called massive atrophy of an extremity involving not only bones but the skin, subcutaneous tissues, tendons and synovial membranes.

All forms of acute bone atrophy develop as the result of disturbed circulation and altered local metabolism. These disturbances lead to the loss of balance between bone formation and bone absorption. The stimuli that cause dilatation of the blood vessels likewise cause an increase in osteoclasts.

The treatment of the condition is concerned primarily with the removal of the original lesion and the improvement of the circulation. This is accomplished in fractures by reduction and correct apposition of fragments and immobilization; in cases complicated with bloody extravasation and edema by elevation of the part. Circulation can be further aided by various

physical therapeutic methods, such as alternating hot and cold immersions, rhythmic elevation and lowering of the limb, massage and heat. Cases refractory to conservative measures may be considerably improved by the operation of ramisectomy or sympathectomy.

POTASSIUM CHLORATE IN DENTIFRICES

Potassium chlorate has long been used as a constituent of mouth washes, gargles, dentifrices and extemporaneous preparations for oral conditions such as stomatitis and mercurial poisoning. Pharmacologic and therapeutic considerations have tended largely toward discrediting such usage. The exploitation of pharmaceutical products containing large amounts of this salt, particularly dentifrices and gargles, continues nevertheless with an apparent disregard of the possible hazards to health.

One dentifrice widely sold in the United States contains more than 41 per cent of this ingredient. In Austria a dentifrice containing more than 10 per cent of potassium chlorate cannot be sold without a physician's order. Reports have appeared pointing out the use of such a dentifrice for suicidal intent, and deaths have occurred when large quantities were swallowed. Much has been made of this fact by writers whose ostensible aim is to protect the public, but they have overlooked the fact that the ordinary daily use of such products does not entail the swallowing of large amounts. The Council on Dental Therapeutics will not accept any dentifrice for daily use which contains potassium chlorate.

A. P. Richardson¹ of the department of pharmacology of Stanford University School of Medicine recently reinvestigated the toxic potentialities of continued administration of chlorate for blood and tissues. In other words, Richardson attacked the problem from the more reasonable angle of chronic poisoning with potassium chlorate rather than from the angle of acute poisoning.

Richardson points out that prolonged use of products containing potassium chlorate, which is a not uncommon practice, might result in sufficient absorption of chlorate, particularly when aided by frictional devices, local lesions, such as ulcers and pus pockets, and other inflammatory states, to produce injurious effects on the blood, kidneys, liver and general health. The administration of potassium chlorate has been a common practice in physiologic laboratories to produce damage to the kidneys.

One of the criteria in the past has been that potassium chlorate formed methemoglobin. Richardson found, however, that continued drinking and repeated intramuscular injections of potassium chlorate in doses larger than those which might be absorbed into the system from ordinary usage of preparations containing

2. Rieder, W.: Die akute Knochenatrophie, *Deutsche Ztschr. f. Chir.* 248: 269 (Dec.) 1936.

1. Richardson, A. P.: *J. Pharmacol. & Exper. Therap.* 60: 101 (Jan.) 1937.

this salt failed to produce demonstrable methemoglobinemia, although considerable illness, loss of body weight and wasting of tissues were produced. This is consistent with a slow and inefficient direct action of chlorate on human blood *in vitro*, in which the production of methemoglobin required first a hemolysis or some corpuscular injury. Accordingly, methemoglobinemia is not the first, or an important, phenomenon in chlorate toxicity except just before death or post mortem. This fact may have a bearing in forensic toxicology.

Whereas sodium chlorate produced the same changes as potassium chlorate, sodium chloride did not cause visceral degeneration, thus indicating a specific action due to the chlorate ion and not to the potassium ion, as postulated by previous workers.²

Even though the test animals survived larger amounts of potassium chlorate than is apt to be absorbed, Richardson points out that the traditional use of potassium chlorate in oral preparations lacks a rational or scientific basis. High concentrations locally may produce protoplasmic injury, as indicated by the slowing down of ciliary activity on strips of frog's esophagus. This salt, Richardson therefore concludes, has no real place in the cosmetic armamentarium. A salt action, when desired, may be obtained with ordinary sodium chloride, which can be used virtually with impunity. The inclusion of potassium chlorate in the current edition of the Pharmacopeia deserves to be reconsidered in the light of these experiments.

AMINO ACIDS AS LIMITING FACTORS IN MALIGNANT GROWTHS

The importance of certain dietary essentials for normal nutrition and growth is well established. As the phenomenon of growth is characterized by a rapid synthesis of body tissue, the need for dietary protein as raw material for this synthesis is apparent. More specifically, the demand for exogenous nitrogen for the building of cellular protoplasm is a manifestation of the need for the individual amino acids, which comprise dietary protein and which are made available to the organism by the processes of digestion and absorption. The pioneer work of Osborne and Mendel clearly demonstrated that, while the body is capable of synthesizing most of these amino acids, this is not true of a certain number of these compounds which must be supplied in the diet and which therefore were termed by those investigators "essential amino acids." Our present knowledge of the rôle of the amino acids in nutrition and growth indicates that nine of the known components of the protein molecule cannot under normal conditions be synthesized by the organism and must be supplied in the diet in order that good nutrition may be maintained and normal growth take place.

In view of the fact that there are some amino acids which are essential for the proliferation of normal tissues, the question arises whether these nitrogenous substances are also essential for the proliferation of malignant tissues. This question is of interest and importance because by a determination of the nature of the various chemical factors that are involved in the normal, continual synthesis of cell proteins it may be possible to secure information that will permit control of the growth of neoplasms. In other words, by restricting a diet with respect to a factor that is essential for normal tissue growth, it may be possible to inhibit neoplastic growth. This important problem is being studied in detail in the Division of Pharmacology of the National Institute of Health, United States Public Health Service, and several interesting reports of some of the investigations are now available.¹ As the indispensability of lysine for normal growth has been definitely established, and since an artificial diet deficient in lysine is fairly simple to prepare, the capacity of this amino acid to limit malignant growth has been investigated. A strain of mice was chosen which exhibits spontaneous neoplasms, since results obtained with this type of growth appear to be of greater significance than those obtained with transplanted tumors. The growth rate of each tumor was determined by estimating the cross sectional area in square millimeters from two dimensions of the tumor, the measurements being made twice weekly. At the end of the experiments a careful necropsy was made; routine histologic examination of the tumor also was conducted. All the tumors in the investigations reported were mammary carcinomas of varying histologic structure. It was clearly demonstrated that, on an adequate stock diet, normal growth of young rats occurred and that on the same diet there was rapid growth of spontaneous mammary carcinoma in mice. However, when the diet was rendered deficient in lysine by subjecting the milk powder of the diet to heat under specified conditions, normal body weight gains and malignant growth were greatly inhibited. The same inhibition of normal growth of young mice and the growth of mammary carcinoma in adult mice could be inhibited by a diet in which gliadin, a protein low in lysine, was the sole source of protein. Furthermore, the addition of lysine to either type of diet resulted in a prompt response in both normal and malignant growth. It seems evident from these studies that lysine in utilizable form is an essential factor necessary for the growth of the mammary carcinoma.

More recently, these results have been extended to other essential amino acids.² The indicated importance of glutathione as a factor influencing the proliferation of cells and the activity of certain cellular enzymes

1. Voegtlin, Carl, and Thompson, J. W.: *Pub. Health Rep.* **51**: 1429 (Oct. 16) 1936. Voegtlin, Carl and Maver, Mary E., *Ibid.* **51**: 1436 (Oct. 16) 1936.

2. Voegtlin, Carl; Johnson, J. M., and Thompson, J. W.: *Pub. Health Rep.* **51**: 1689 (Dec. 4) 1936.

2. Ulrich, J. L., and Shternov, V. A.: *J. Pharmacol. & Exper. Therap.* **35**: 1 (Jan.) 1929.

led to a consideration of whether or not, under certain conditions, glutathione can influence the proliferation of neoplasms. As glutathione is a tripeptide composed of cystine, glutamic acid and aminoacetic acid (glycine), and since a diet deficient in cystine and methionine does not permit normal growth of young rats, the Washington investigators have first studied the problem of whether neoplastic growth can be inhibited by feeding adult animals with tumor on a diet deficient in cystine and methionine. It was demonstrated that it is possible by this type of diet to cause a slowing or even cessation of the growth of a typical neoplasm. The same diet inhibits the normal growth of young mice. Furthermore, it was shown that following a period of inhibited tumor growth the administration of either cystine or glutathione causes a marked stimulation of tumor growth. It would seem, therefore, that with respect to the growth-stimulating response to cystine or glutathione there is no essential difference between normal growth of young mice and rats on the one hand and the growth of the spontaneous mammary carcinoma on the other. Although a more detailed study, with perhaps statistical treatment of the data, is desirable, evidence appears to be accumulating which indicates that the proliferation of this typical malignant tumor can be inhibited by diets deficient in certain essential amino acids. It will be of interest to determine whether other types of malignant tumors, especially those induced by carcinogenic substances, behave similarly.

Current Comment

THE EFFECT OF THEELIN ON BLEEDING IN NONHEMOPHILIC PATIENTS

In previous discussions of the use of estrogens in the treatment of hemophilia in these columns¹ it has been pointed out that, although they appeared to be of some value in some instances, the results have been negative in the majority of cases thus far described. Recently the effect of theelin on hemorrhage in four nonhemophilic patients has been studied.² Two of the patients were boys aged 3 and 12 years, one was a man aged 32, and one was a woman aged 39. There was no history indicative of hemophilia in any case and the clotting time of each patient was normal prior to operation: tonsillectomy in three cases, and both tonsillectomy and adenoidectomy in the other. After periods of from ten hours to six days following the operation, however, there occurred bleeding of a diffuse capillary oozing type, which could not be controlled by the usual means. Treatment with theelin was then tried and the result in the four cases was rather striking. Within twenty to thirty-five minutes after the subcutaneous injection of from 25 to 50 rat units of theelin, bleed-

ing ceased and did not recur. Although these observations are indeed suggestive, further careful studies in a larger number of subjects is needed before conclusions are warranted regarding the possible favorable effect of estrogens in the treatment of hemorrhage in non-hemophilic patients.

A COMPLICATION FOLLOWING TREATMENT WITH SULFANILAMIDE

With the introduction into therapeutics of a new drug that produces spectacular results there may be disadvantages that do not become obvious until after the drug has been in use for some time. Experiences with dinitrophenol, beta-aminopropylbenzene, cinchophen and mandelic acid will be remembered. While sulfanilamide at first was believed to be nontoxic, several reports now indicate that sulfhemoglobinemia may be an occasional complication of its use in treatment. Discombe¹ at St. Bartholemew's Hospital, London, calls attention to this in six of seven patients in the hospital who had received more than 5 Gm. of the prontosil brand of sulfanilamide. Three of these patients showed marked cyanosis. The cyanosis which is caused by sulfhemoglobin may be spectacular and alarming, but it does not produce any serious consequences if the drug is stopped as soon as it is noticed. All of the six patients so affected were recovering at the time of Discombe's report. If, however, the total hemoglobin in a case complicated by sulfhemoglobinemia should fall below about 30 per cent (by the Haldane scale), the condition might be dangerous. Cyanosis probably could not occur then; and yet the drug responsible for the sulfhemoglobinemia might be continued until over half of the total hemoglobin present in the patient's blood was changed to the inert form. Under such circumstances, the plight of a patient suffering from a streptococcal infection whose active hemoglobin amounted to about 15 per cent would be hazardous. An interesting fact is that four of the seven patients had been given frequent doses of magnesium sulfate. Another patient had been given two doses of magnesium sulfate, and another received no magnesium sulfate by mouth but did have dressings of sodium sulfate applied to a large gangrenous area. The one patient who did not show any abnormal pigments in the blood even after long continued sulfanilamide treatment had not received any sulfates by mouth or as a dressing. It has been suggested that some connection exists between the development of sulfhemoglobinemia and the use of magnesium sulfate in patients who are under treatment with sulfanilamide; as yet this can neither be confirmed nor denied. Discombe's report suggests that a careful watch for the development of cyanosis is not sufficient precaution against sulfhemoglobinemia; in addition the total hemoglobin should be determined and the patient's blood examined at regular intervals of every few days. The possibility of an unrecognized occurrence of sulfhemoglobinemia should be borne in mind and the administration of magnesium or sodium sulfate to patients under treatment with sulfanilamide probably should be forbidden until more information is available.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Medical Conference.—A medical conference for general practitioners was held in Oakland recently under the auspices of the Alameda County Institutions Commission, the Alameda County Medical Association, staffs of hospitals in Alameda County and the University of California Extension Division, with Dr. Benjamin W. Black in charge. The program was designed to cover the specialties for the general practitioner.

Hospital News.—The East Bay Hospital Conference, composed of all approved hospitals in Alameda County, held its annual meeting recently at Peralta Hospital, Oakland. The speakers included Drs. Robert T. Legge, Berkeley, on "Control of Venereal Disease," and Benjamin W. Black, Berkeley, "Relationship of the County Hospital to the Voluntary Hospitals."—The Seaside Hospital of Long Beach, Ltd., through the action of its stockholders and board of directors, has changed its corporate status and its name. Henceforth it will be operated as a nonprofit institution, governed by a board of trustees and using the name "Seaside Memorial Hospital."

COLORADO

Spring Clinics.—The Pueblo County Medical Society will conduct its fourth annual spring clinics in Pueblo, May 5-7, under the auspices of the Colorado State Medical Society. The program will include symposiums on syphilis, respiratory diseases of childhood, peptic ulcer and gallbladder. The guest speakers will include Dr. Delmar Foster Bice, Yakima, Wash., on "State Medicine," and Dr. Bradford James Murphy, Colorado Springs, "Mental Hygiene." Other speakers will include the following, all of Pueblo:

Dr. Earle H. Corry, Exfoliative Dermatitis Following Eczema.
Dr. Joseph W. Craighead, The Cardiac Problem.
Dr. Clarence E. Earnest, The Handling of Eye Injuries.
Dr. Scott A. Gale, Treatment of Gynecologic Conditions by Elliott Treatment.
Dr. Harold T. Low, Paralytic Bladder in Spinal Cord Injuries.
Dr. William Senger, Advances in the Treatment of Inguinal Hernia.

CONNECTICUT

Twenty-Five Years' Service.—Dr. Charles J. Bartlett has retired as a commissioner of the New Haven Board of Health after twenty-five years' service, according to *Health*, the department's monthly bulletin. The February issue was dedicated to safe milk, which has been Dr. Bartlett's chief interest during his association with the board. Aged 72, Dr. Bartlett graduated from Yale University School of Medicine in 1895. He is emeritus professor of pathology at his alma mater. In 1918 he was president of the Connecticut State Medical Society and in 1935 of the Connecticut Medical Examining Board and the Connecticut Association of Public Health and Clinical Laboratories. He will continue to serve the board as consultant.

DELAWARE

Society News.—Dr. Eldridge L. Eliason, professor of clinical surgery, University of Pennsylvania School of Medicine, Philadelphia, addressed the New Castle County Medical Society at the Delaware Academy of Medicine, Wilmington, March 16, on the gallbladder.

DISTRICT OF COLUMBIA

Prize to Dr. du Vigneaud.—Vincent du Vigneaud, Ph.D., professor of biochemistry, George Washington University School of Medicine, has received the Hillebrand prize for 1936 of the Chemical Society of Washington. The award, which was presented March 11, was made in recognition of Dr. du Vigneaud's contributions to the chemistry of biologically significant sulfur compounds.

Society News.—The Medical Society of the District of Columbia, Washington, was addressed April 14 by Drs. George B. Tribble on "Nose and Throat Manifestations in the Acute Infections of the Mononucleosis Type" and Ralph M. LeComte, "Renal Tuberculosis."—Sir Henry H. Dale, London, will address the Academy of Medicine of Washington, May 18, on

the chemical transmission of the nerve impulse. The academy adopted a resolution, March 9, in memory of the late Dr. William A. White, who was the first president of the academy.

ILLINOIS

Society News.—Dr. Francis E. Sencar, Chicago, will address the Adams County Medical Society, May 10, in Quincy on "Diagnosis and Treatment of Early Syphilis." A symposium on intravenous medication was presented before the society April 12 by Drs. Milton E. Bitter, James F. Merritt, Warren F. Pearce and Walter M. Whitaker, all of Quincy.—Dr. John J. Hammond, St. Louis, discussed pneumonia before the Madison County Medical Society in Highland, April 2.

Chicago

Dr. Harmon to Direct Program for Crippled Children.—Dr. Paul H. Harmon, instructor in orthopedic surgery, University of Chicago, has been appointed director of the crippled children's bureau of the Illinois Department of Public Welfare, with offices in Springfield, effective April 1. The university has granted Dr. Harmon a leave of absence to organize the state's program for crippled children, which will be financed by social security funds. The project will include a census of crippled children; provision for the care of indigent crippled children, and an orthopedic field nursing and follow-up program.

Rongetti Denied Freedom.—Dr. Amante Rongetti, who is serving sentence for manslaughter in the state prison at Joliet, was denied a writ of habeas corpus by Judge Edwin L. Wilson of the Will County circuit court at Joliet, March 25, it is reported. Dr. Rongetti was received at the penitentiary Feb. 10, 1934. In his first trial, on the charge of causing a death through an illegal operation, Rongetti was sentenced to death, but at the second trial the supreme court committed him to the penitentiary for from one to fourteen years. Feb. 6, 1934, a few days before his entry into Joliet, Rongetti completed a three year sentence in the federal prison at Leavenworth, Kan., for violation of the Harrison Narcotic Act.

Society News.—The Chicago Urological Society was addressed March 25, among others, by Dr. Harry E. Kasten, Beloit, Wis., on "Metastasis in Hypernephroma." Dr. Homer G. Hamer, Indianapolis, will address the society, April 22, on "Diagnosis, Differential Diagnosis and Treatment of Metastatic Infections of the Kidney" and Dr. Vincent J. O'Connor will discuss the etiology of the subject.—The Chicago Gynecological Society was addressed, March 19, among others, by Drs. George C. Finola on "Bone Changes in the Fetus Following the Administration of Dicalcium Phosphate and Viosterol to the Pregnant Mother," and Morris Edward Davis and Sarah A. Pearl, "Biology of the Human Vagina During Pregnancy."—Dr. Edward A. Skolnik addressed the Jewish Physicians Fellowship Club of Chicago and Suburbs March 8 on "A Panoramic View of Syphilis."—The Chicago Orthopaedic Society was addressed, April 9, by Drs. Harry E. Thompson, Tucson, Ariz., on "Chronic Atrophic Arthritis," and Sumner L. S. Koch, "Infections of the Hand in a General Hospital."

INDIANA

Personal.—Dr. Verne K. Harvey, Indianapolis, has been reappointed director of the Indiana State Board of Health.

Child Health Day.—An organization has been perfected in Indiana to carry out a uniform observance of Child Health Day, May 1. The program chairmen of the county medical societies will draw up programs in cooperation with the Indiana Advisory Health Council, the medical association and the state board of health. The work will be coordinated through newspaper publicity, clinics and school health and radio programs, the state medical journal announcements.

Maternal Mortality.—The Indiana State Board of Health early in March launched a campaign to reduce maternal mortality, the work to be financed with funds recently made available under the social security act. The bureau of child and maternal health, which will supervise the project, was created last year with Dr. Howard B. Mettel, Indianapolis, as director. According to the state board's bulletin, in Indiana during the last five years 4,000 women were unattended by physicians at childbirth.

IOWA

Plan for Syphilis Control.—The committee on venereal disease control of the Iowa State Medical Society and the state board of health formulated plans for the state's participation in the national campaign against syphilis at a meeting January 17. The program will include the establishment of clinics for patients unable to pay for private treatment, and

the development of an adequate follow-up nursing service. One phase of the plan became effective February 1, when approved arsenicals and bismuth preparations were made available on request, in minimum doses of twenty each, to patients in the acute infectious stage. After July 1 it will be possible to provide drugs required for adequate treatment of all cases of syphilis, irrespective of economic status, without cost, on request of the attending physician. Pending favorable legislation, it was thought that by April 1 a statewide free laboratory diagnostic service would be available. The plan provides for the distribution of antisyphilitic drugs through local druggists on a carrying charge of 10 per cent.

KANSAS

Society News.—Dr. Claude S. Beck, Cleveland, discussed "Recent Advances in Cardiac Surgery" before the Wyandotte County Medical Society, Kansas City, March 16. The society was addressed March 2 by Drs. William W. Abrams, Kansas City, on "Epilepsy and Its Treatment" and Paul M. Krall, Kansas City, "Physiologic Considerations and Their Possible Relationship to Cardiovascular Disorders."

Medical Service Bureau an Experiment.—The Sedgwick County Medical Society and the Wichita Community Chest have set up, as an experiment, a medical service bureau which will be located in the offices of the county society. Control will be vested in a board of six members, three from the society and three from the Community Chest. The latter has contributed \$1,000 for the services of a case worker and the medical society is furnishing equipment and office space. According to the *Medical Bulletin*, the patient referred to the bureau by either a physician or a recognized social agency will be interviewed by the case worker, who, after a study of the patient's income and his budget requirements, will determine the amount he can pay for medical services over a twelve months period. A report will be given to the physician chosen by the patient and he in turn will arrange a satisfactory fee and plan of payment. The experiment will be conducted for eight months.

LOUISIANA

State Medical Meeting at Monroe, April 26-28.—The annual meeting of the Louisiana State Medical Society will be held in Monroe, April 26-28, under the presidency of Dr. Hiram W. Kostmayer, New Orleans. The public is invited to the meeting of the section on public health and sanitation, when Sir Aldo Castellani will discuss "Preventive Aspects of Medical Service Among the Italian Forces in the Ethiopian War." Guest speakers will include:

- Dr. Warren H. Cole, Chicago, Acute Pancreatitis.
- Dr. Jean Paul Pratt, Detroit, Pelvic Conditions Simulating Appendicitis.
- Dr. Ernest Sachs, St. Louis, Surgery in Brain Tumors.
- Dr. Melvin S. Henderson, Rochester, Minn., Internal Fixation and Fractures of the Neck of the Femur.
- Dr. Andrew B. Rivers, Rochester, Minn., The Cause of Dyspepsia at Various Ages.
- Dr. Reuben A. Brown, Montgomery, Ala., A Practical Tuberculosis Case Finding Program.

MASSACHUSETTS

University News.—Dr. Henry E. Sigrist, Baltimore, discussed "The Role of the Professional Organization in Social Action" before the Boston University Medical Society, March 29.—At a meeting of the Harvard Medical Society in Boston, April 6, Dr. Albert Bessemans, former rector of the University of Ghent, Belgium, spoke on "The Invisible Form of the Syphilitic Virus."—Dr. Louise Eisenhardt, research assistant in pathology, Yale University School of Medicine, New Haven, delivered the annual alumni lecture at Tufts College Medical School, Boston, April 6; her subject was "Observations upon Patients After Operation for Intracranial Tumor."

Scholarships at Harvard Medical School.—With a view to lessening the burden of the worthy student, plans to establish additional scholarships at Harvard University Medical School are under consideration, according to the recent annual report of the dean, Dr. Charles Sidney Burwell. With a student enrolment of 526, the medical school at present gives about \$12,000 a year in scholarships, averaging \$250 each to about fifty students, student fellowships totaling \$1,800 to about six students annually in return for investigative work, and loans of about \$10,000 a year. Under the new prize scholarship plan, at least ten students in each of the four classes would receive the awards. The chief objective of the scholarship system is to relieve the brilliant student from the necessity of supporting himself by outside work, with the stipends adjusted to each person's need. Last year the school admitted a standard class of 125 students from 800 applicants.

MICHIGAN

Society News.—The annual banquet of the Phi Beta Pi Medical Fraternity will be held at the Fort Shelby Hotel, Detroit, April 24.—Dr. Russell D. Herrold, Chicago, read a paper before the Ingham County Medical Society, Lansing, March 16, on "The Criteria of Cure in Venereal Infection."

Hospital News.—A new \$400,000 hospital was opened in Port Huron, February 25, following a dinner given by the St. Clair County Medical Society. The speakers included Drs. Angus McLean, James M. Robb, William J. Cassidy and Alpheus F. Jennings, all of Detroit; Dr. Thomas E. De Gurse, mayor of Marine City, and Dr. Theodore Heavenrich, Port Huron. Dr. Alexander J. MacKenzie, chief of staff of the hospital, was toastmaster. The hospital was financed in part by a PWA grant.

Conferences on Communicable Diseases.—The Wayne County Medical Society, the Detroit Tuberculosis Sanatorium Association and the Detroit Department of Health are sponsoring graduate conferences on tuberculosis and acute communicable diseases. They began March 31 and will continue Wednesday mornings to April 28, at the Herman Kiefer Hospital, Detroit. The speakers include:

- Dr. Joseph S. Baird, Pittsburgh, Scarlet Fever.
- Dr. Henry S. K. Willis, Northville, Tuberculin and Tuberculin Testing.
- Dr. Russell L. Cecil, New York, Pneumonia.
- Dr. Eugene L. Opie, New York, Tuberculosis and the Family.
- Dr. Archibald L. Hoyne, Chicago, Meningitis.
- Dr. Harold N. Cole, Cleveland, Syphilis.
- Dr. Jacob J. Singer, St. Louis, Tuberculosis.

MINNESOTA

Industrial Medical Conference.—A Northwest Industrial Medical Conference will be a feature of the annual session of the Minnesota State Medical Association in St. Paul, May 2-5. The conference will open at the St. Paul Auditorium, Wednesday morning, May 5, with an address of welcome by Mr. F. T. Starkey, St. Paul, chairman, Minnesota Industrial Commission. Other speakers will include:

- Dr. Maxwell J. Lick, Erie, Pa., president, Medical Society of the State of Pennsylvania, Differential Diagnosis in Acute Abdominal Tragedies.
- Dr. Michael L. Mason, associate professor of surgery, Northwestern University Medical School, Chicago, Pitfalls in the Management of Hand Infections.
- Dr. Wallace H. Cole, St. Paul, Hand and Wrist Injuries.
- Dr. Joseph R. Kuth, Duluth, Back Injuries.
- Dr. Winchell McK. Craig, Rochester, Adequate and Inadequate Treatment of Head Injuries.
- Dr. Henry W. Meyerding, Rochester, Fracture Dislocation of the Shoulder.
- Dr. Bertram S. Adams, Hibbing, Injuries to the Thigh.
- Dr. Harry B. Macey, Rochester, New Automobiles and New Fractures.
- Dr. Arthur A. Zierold, Minneapolis, Peripheral Nerve Injuries.
- Dr. Robert F. McGandy, Minneapolis, Review of the Treatment of Burns.
- Dr. Carl C. Chatterton, St. Paul, Certain Derangements of the Knee Joint.
- Dr. Otto W. Yoerg, Minneapolis, Treatment of Os Calcis Fractures.
- Dr. Frank H. Krusen, Rochester, Physical Therapy in Relation to Industrial Medicine.

Dr. Alfred W. Adson, Rochester, president of the state medical association, will act as chairman of a panel discussion concluding the session. Tuesday evening an "industrial dinner" will be held at the Hotel Lowry. The speakers will be Governor Elmer A. Benson, St. Paul; Dr. Adson, and Mr. Voyta Wrabetz, Madison, Wis., chairman of the Industrial Commission of Wisconsin, whose subject will be "Prompt Reporting and Cooperation with Commissions."

MISSOURI

Annual Campaign Against Diphtheria.—Members of the Jackson County Medical Society and the Kansas City department of health are cooperating in their annual campaign against diphtheria. Physicians during April are giving in their offices one injection of alum precipitated toxoid for immunization, charging a fee of \$1 and using material supplied by the department of health. In 1936 there was not a single death attributed to diphtheria, the first time in the city's history.

Fifty Years in Practice.—Dr. Isadore J. Wolf, professor of medicine, University of Kansas School of Medicine, Lawrence-Kansas City, Kan., and president of the staff of Menorah Hospital, was guest of honor at a dinner, March 15, in celebration of his completion of fifty years in the practice of medicine. Dr. Fred Irwig presented Dr. Wolf with a gold watch on behalf of the hospital staff, and speakers included Rabbi Harry H. Mayer and Dr. Logan Clendening. Dr. Clinton K. Smith presided. Dr. Wolf is 73 years of age. He graduated from Ludwig-Maximilians University Faculty of Medicine, Munich, Germany, in 1887.

NEBRASKA

Society News.—A symposium on oxygen therapy was presented at the meeting of the Omaha-Douglas County Medical Society, March 9, by Dr. Fenimore E. Davis, Kansas City, Kan.; Dr. Ford K. Hick, Chicago, and Mr. J. I. Banash, consulting engineer, Chicago.—Dr. John C. Thompson, Lincoln, addressed the Platte-Loup Valley Medical Society in Columbus, recently, on etiology and treatment of cardiac diseases, and Dr. Joseph J. Hompes, Lincoln, showed eye clinics in India in motion pictures.

NEW HAMPSHIRE

Personal.—Dr. Chancey Adams, Concord, has been appointed physician of the state prison, succeeding the late Dr. Edward J. Delaney.

Lectures on Obstetrics.—The New Hampshire Medical Society and the state board of health are sponsoring a series of lectures on obstetrics as part of a statewide campaign to reduce infant and maternal mortality. The centers of instruction are Dover, Manchester, Hanover and Berlin. The lectures are given by Boston physicians.

NEW JERSEY

State Medical Meeting at Atlantic City.—The annual meeting of the Medical Society of New Jersey will be held in Haddon Hall, Atlantic City, April 27-29. General sessions will be held Tuesday afternoon and Thursday morning and sectional meetings Wednesday morning and Thursday afternoon. Speakers at the general sessions will be:

Dr. William P. Thompson, New York, *Indications for Splenectomy*.
Dr. Allen O. Whipple, New York, *Results of Splenectomy in Some 100 Cases*.

Dr. William Hall Lewis Jr., New York, *Medical Aspects of Coma*.

Dr. John Arthur MacLean Jr., New York, *Surgical Management of Coma*.

Dr. James Burns Amberson Jr., New York, *Selection of Treatment for the Tuberculous Patient*.

Dr. Adrian V. S. Lambert, New York, subject not announced.

Dr. Victor Carabba, New York, *Electrosurgical Aseptic Intestinal Anastomosis*.

Dr. Frederick C. Holden, New York, *Again—Maternal Mortality Problems*.

Drs. William Howard Barber and Anthony S. Bogatko, New York, *Failures After Gastrojejunostomy*.

Dr. Emery A. Rovenstine, New York, *Oxygen Therapy by Oropharyngeal Insufflation*.

Drs. Rita V. S. Finkler and Milton Friedman, Newark, *Treatment of Pituitary and Ovarian Dysfunction*.

Dr. Hugh H. Young, Baltimore, subject not announced.

Dr. Stanley R. Woodruff, Jersey City, *Management of Ureteral Calculus*.

There will be a general public health session Tuesday evening at which the speakers will be Drs. Charles Gordon Heyd, New York, President of the American Medical Association; Thomas Parran, surgeon general, U. S. Public Health Service, Washington, D. C., and Howard W. Haggard, New Haven, Conn.

NEW YORK

Dr. Munger Leaves Grasslands Hospital.—Dr. Claude W. Munger, director of Grasslands Hospital, Valhalla, for thirteen years, resigned March 18 to become director of St. Luke's Hospital, New York. Before going to Grasslands, Dr. Munger was director of Blodgett Memorial Hospital, Grand Rapids, Mich., and previous to that, superintendent of Columbia Hospital, Milwaukee. He is at present president of the American Hospital Association. He was graduated from Rush Medical College, Chicago, in 1916.

Society News.—Drs. Francis O. Harbach and I. Harris Levy addressed the Onondaga Medical Society, Syracuse, March 2, on "Carcinoma of the Male Urethra" and "Hypotension" and Dr. William A. Groat gave the first of a new series of reports on "What's New," discussing "What's New in Diabetes."—Dr. John G. Fred Hiss, Syracuse, addressed the Oswego County Medical Society, Oswego, recently, on "Heart Problems in General Practice."—Dr. Edward S. Godfrey Jr., Albany, state commissioner of health, addressed the Rochester Academy of Medicine, April 1, on "The Meaning of Public Health."—Dr. James G. Carr, Chicago, addressed the Niagara County Medical Society, Niagara Falls, recently, on diagnosis and treatment of coronary occlusion.—Dr. Wildridge C. Thompson Jr., Albany, addressed the Ulster County Medical Society at its winter meeting in February on diagnosis and treatment of early syphilis.—Dr. John F. Erdmann, New York, addressed the Medical Society of the County of Westchester, White Plains, March 16, on "The Treatment of Cholecystitis, Cholelithiasis and Cholangitis."

New York City

Long Island Alumni Day.—The annual Alumni Day of Long Island College of Medicine will be held April 24. Dr. Cassius H. Watson, medical director, American Telephone and Telegraph Company, will speak at a morning session and Dr. George H. Gehrmann, medical director of the E. I. du Pont de Nemours Company, Wilmington, Del., at the afternoon meeting. The annual banquet will be at the Columbus Club, with Mr. Grover A. Whalen as the speaker.

Society News.—Drs. Tinsley R. Harrison, Nashville, Tenn., and Alfred E. Cohn addressed the New York Heart Association at a joint meeting with the section of medicine of the New York Academy of Medicine, March 16, on "Cardiac Dyspnea" and "Cardiac Diseases—Nosology and Public Health."

Changes in City Hospitals.—Dr. Edward M. Bernecker of the staff of Metropolitan Hospital on Welfare Island, who recently placed first in a civil service examination for the position of general medical superintendent in the New York City Department of Hospitals, took office March 15. Dr. Bernecker succeeds Dr. Adam Eberle, who has been made senior general medical superintendent. Dr. Emanuel Giddings, medical director of Morrisania Hospital, has been transferred to the same position at Kings County Hospital. Dr. Henry Greenberg, head of Fordham Hospital, succeeded Dr. Giddings at Morrisania and Dr. Stephen H. Ackerman has gone from Coney Island Hospital to Fordham. Dr. Charles G. McGaffin was placed in charge at Coney Island.

Personal.—Dr. Simon Flexner, director emeritus of the Rockefeller Institute for Medical Research, has been elected a trustee of Johns Hopkins University, Baltimore. Dr. Flexner has also been elected a foreign associate of the Academy of Sciences, Institute of France, to succeed the late Emanuele Paterno, Marquis di Sessa, Palermo, Sicily.—Dr. Wilbur A. Sawyer of the Rockefeller Foundation has been appointed a member of the National Advisory Health Council of the U. S. Public Health Service.—Dr. Aaron Arnold Karan, assistant director of the Jewish Hospital of Brooklyn, has resigned to become superintendent of the Workmen's Circle Sanatorium, Liberty, N. Y. Dr. Karan succeeds Dr. Bruno S. Harwood, who will enter private practice in New York.

Unlicensed Practitioners Convicted.—The New York State Board of Medical Examiners reports that Deidrich Meinking, Brooklyn, was convicted, February 27, of practicing medicine without a license and sentenced to three months in the workhouse. Martha Ferdinand at the same time was sentenced to serve three months in the workhouse, with the sentence suspended, and to pay a fine of \$100, in default of the payment of which she was to serve twenty days in the workhouse. Richard Schlessinger was sentenced to three months in the workhouse, with the sentence suspended during good behavior. Benjamin Peltz was sentenced to three months in the workhouse, with sentence suspended during good behavior. Charles H. Worch, a Brooklyn chiropractor, was sentenced to thirty days in the workhouse or to pay a fine of \$250. Raymond E. Hummel, Wantagh, L. I., associated with the "Eastern Chiropractic Institute Clinic," was recently sentenced to six months in the workhouse for practicing without a license. Anna Brauer was sentenced to three months in the workhouse on a similar charge, with the sentence suspended.

NORTH CAROLINA

New Health Officers.—Dr. Walter Raleigh Parker, Woodland, has been appointed health officer of Northampton County to succeed Dr. Marion H. Seawell, Jackson, resigned. Dr. Wayland N. McKenzie, Albemarle, has been chosen to head a new health department in Stanly County to be opened in July. Dr. Harold C. Whims, Waxhaw, has succeeded Dr. Robert M. Bardin, Rutherfordton, as health officer of Rutherford County.

Two New Hospitals.—A new building for Rex Hospital, Raleigh, with a capacity of 200 beds, was opened for inspection by the public March 2. The necessary funds came from a bond issue of \$287,000 and a PWA grant of \$100,000. A campaign for public subscriptions raised \$25,000 for equipment, but it is said that another \$25,000 is needed.—The new Forsyth County Hospital for the Indigent near Winston-Salem has been completed and was open for public inspection March 1-2. There are seven units in the institution, the administration building, hospital ward, a ward for mental patients, dining halls, living quarters, laundry and garage. The hospital unit contains forty-two beds. The total cost of the group was \$230,000, of which \$102,024 was a PWA grant. A new sanatorium for tuberculous patients was recently completed on the county farm at a cost of \$250,000. Dr. Joseph Lindsay Co. Jr., county physician, is executive supervisor of the county hospital.

OHIO

Veteran Physicians Honored.—The staff of Polyclinic Hospital, Cleveland, gave a testimonial dinner March 6 in honor of Dr. Albert F. Spurney, one of the founders of the hospital, who has completed fifty years of medical practice. Dr. Spurney graduated from Western Reserve University School of Medicine in 1887 and was at one time instructor in therapeutics at the Physicians and Surgeons College. At various times he was on the staffs of the Cleveland General, Cleveland City and Saint Luke's hospitals.—Dr. James F. Leeper, McConnellsville, was the guest of honor at a meeting and banquet of the Morgan County Medical Society in January as the oldest practicing physician in the society. Dr. Lee Humphrey, Malta, was toastmaster. Dr. Leeper is 78 years old and graduated from the old Starling Medical College, Columbus, in 1878.

State Medical Meeting at Dayton April 28-29.—The ninety-first annual meeting of the Ohio State Medical Association will be held in Dayton, April 28-29, with headquarters at the Hotel Biltmore. Guest speakers who will address general sessions are:

Dr. Walter C. Alvarez, Rochester, Minn., Useful Hints in the Treatment of Gastro-Intestinal Disease.
Weston A. Price, D.D.S., Cleveland, New Light on Modern Physical Degeneration from Field Studies Among Primitive Races.
Dr. Frank E. Adair, New York, Preoperative Radiation in Operable Cancer of the Breast.
Dr. Fred W. Rankin, Lexington, Ky., The Hopeful Prognosis in Cancer of the Lower Gastro-Intestinal Tract.

Dr. Harry S. Gradle, Chicago, will address the section on eye, ear, nose and throat on "Diagnosis of Early Cases of Compensated Glaucoma." Among Ohio physicians who will appear on the program are:

Dr. Jesse Fremont Bateman, Columbus, The American Disease.
Dr. Samuel O. Freedlander, Cleveland, Total Pneumonectomy.
Drs. Charles A. Doan, Carl V. Moore and Thomas F. Ross, Columbus, Differential Diagnosis and Therapeutic Rationale of the Anemic States.
Dr. William B. Chamberlin, Cleveland, Conditions in Otolaryngology of Interest and Importance to the General Practitioner.
Dr. Clare R. Rittershofer, Cincinnati, Clinical Observations on Anemia in Children.
Dr. William H. Weir, Cleveland, Abdominal Panhysterectomy.

The annual banquet will be held Thursday evening, April 29, with Dr. Howard V. Dutrow, Dayton, as toastmaster. Lloyd C. Douglas, D.D., Los Angeles, author of "Magnificent Obsession" and "Green Light," will be the speaker.

OREGON

Personal.—Dr. Norman E. Irvine, Lebanon, has been elected president of the state board of health. Dr. Irvine was president also in 1933.—Dr. Elsworth L. Gardner, Portland, has been appointed health officer of Lane County, succeeding Dr. Alstrup N. Johnson, who resigned.—Dr. August E. Bostrom, DeSmet, S. D., has joined the staff of the state board of health in Portland.

PENNSYLVANIA

Annual Seminar in York.—The third annual graduate seminar course conducted by the medical societies of York and Adams counties was begun at York Hospital, March 18, and will continue on alternate Thursdays till May 27. The lecturers, all of Philadelphia, are:

Dr. Eldridge L. Eliason, Treatment of Fractures, March 18.
Dr. Edward A. Schumann, Obstetrics, April 1.
Dr. Vaughn C. Garner, Syphilis, April 15.
Dr. Richard A. Kern, Allergy, April 29.
Dr. George Harlan Wells, Pneumonia and Diabetes Mellitus, May 13.
Dr. William D. Stroud, Diseases of the Heart, May 27.

Philadelphia

School Health Director Honored.—Dr. Walter S. Cornell, director of the division of medical inspection in the Philadelphia public schools, was the guest of honor at a dinner February 9 celebrating his twenty-fifth anniversary in that position. Dr. Cornell is 60 years old and graduated from the University of Pennsylvania School of Medicine in 1901. He founded the system of medical inspection in the schools.

Society News.—Dr. Alexander Randall delivered the annual oration of the Philadelphia Academy of Surgery, March 1, on "Observations on the Origin and Growth of Renal Calculi."—William U. Gardner, Ph.D., New Haven, Conn., addressed the Pathological Society of Philadelphia, March 11, on "Influence of Estrogenic Hormones in the Stimulation of Abnormal Growths" and Dr. Helen Ingleby, "Etiology of Plasma Cell Mastitis."—A. Irving Hallowell, Ph.D., associate professor of anthropology, University of Pennsylvania, among others, addressed the Philadelphia Psychiatric Society, March 12, on "Normal and Abnormal Fears in a Native

Indian Community."—A symposium on pernicious anemia was presented at a meeting of the Philadelphia County Medical Society March 24 by Drs. Max M. Strumia, Thomas Fitz-Hugh Jr., Michael A. Burns and William Egbert Robertson.

Pittsburgh

New Building for Mellon Institute.—A new home for the Mellon Institute for Industrial Research will be dedicated May 5-9, to replace the building on the campus of the University of Pittsburgh, where the institute has been for twenty-two years. The new building is nine stories high, though the four lower floors are below ground level. The style is Ionic, with columns around all four sides. It covers most of a city block. Mellon Institute was founded in 1913 by Andrew W. Mellon and Richard B. Mellon, an outgrowth of a trial of the fellowship system at the University of Pittsburgh. Since the beginning in 1911 there have been 1,150 industrial fellowships on 279 subjects of technology. Sixty-four fellowships are operating at present. It is expected that the new building will make possible expansion of present research and the development of new fields, especially in pure science. Edward R. Weidlein, Ph.D., is director of the institute.

RHODE ISLAND

Society News.—Drs. Cecil C. Dustin and Herman C. Pitts addressed the Providence Medical Association, April 5, on "Brucella Infections in Man" and "Sickness Insurance in Foreign Countries" respectively.—Dr. Mario A. Castallo, Philadelphia, addressed the Malpighi Medical Club, Providence, March 30, on "Management of Syphilis and Gonorrhea Complicating Pregnancy."

Building Program at State Mental Hospital.—Nineteen building projects are under way at the State Hospital for Mental Diseases, Howard, as a part of a \$12,000,000 emergency public works program in state institutions. Among the new buildings is the psychiatric clinic to accommodate 120 patients, the medical and surgical building for 135 and a tuberculosis building for ninety. There will also be two new wards for patients with curable mental disorders, two for those with advanced mental disturbances, an administration building, dormitories for men and women employees, a staff house and several cottages for married physicians, and various service buildings. The women employees' dormitory was completed and dedicated in October 1936 and it is expected that other buildings will be finished at intervals during the coming year. Dr. Seth F. H. Howes is superintendent of the state mental hospital.

TENNESSEE

Society News.—Drs. Ola E. Ballou and James Sam Taylor presented papers at a meeting of the Anderson County Medical Society, Clinton, March 1, on diseases of the myocardium.—Dr. Albert Weinstein, Nashville, addressed the Davidson County Medical Society, Nashville, April 6, on "Methyl Chloride (Refrigerator Gas) Poisoning."—Dr. Talbert C. Crowell, Chattanooga, discussed "Influences of Weather on Hay Fever and Asthma Patients" at a meeting of the Hamilton County Medical Society, Chattanooga, April 1.—Dr. Robert B. Wood, Knoxville, addressed the Knox County Medical Society, Knoxville, March 2, on "Nontuberculous Pulmonary Infections."—Dr. Launcelot Minor Blackford, Atlanta, addressed the Washington County Medical Society, April 2, on "Syphilis of the Aorta."

Professors Appointed.—Major George W. Reyer, Medical Corps, U. S. Army, has been appointed professor of military science and tactics with the reestablishment of the medical unit of the Reserve Officers Training Corps at Vanderbilt University School of Medicine, Nashville. Major Reyer was graduated from Vanderbilt in 1917 and has recently been at the Army and Navy General Hospital, Hot Springs National Park, Ark. Dr. Rudolph H. Kampmeier, recently clinical professor of medicine at the Louisiana State University School of Medicine, New Orleans, has been appointed assistant professor of medicine in the Vanderbilt medical faculty. Dr. Kampmeier was graduated from the State University of Iowa College of Medicine in 1923.

VIRGINIA

Society News.—Dr. Russell L. Cecil, New York, addressed the Richmond Academy of Medicine, March 23, on pneumonia.—The Virginia Mental Hygiene Society was organized in February, with Dr. Beverley R. Tucker, Richmond, as president.—Dr. Robert Finley Gayle Jr., Richmond, was elected president of the Virginia Neuropsychiatric Society at a meeting in Richmond in January. Dr. Thomas N. Spessard, Roanoke, was made secretary.

Medical Progress in Richmond.—In connection with a celebration of the two hundredth anniversary of Richmond and the centennial of the Medical College of Virginia, an exhibit is being prepared to show to the public as well as to the medical profession the progress of medicine in Richmond during the city's history. Dr. Wyndham B. Blanton is in charge of the exhibit, which will be set up in the Richmond Academy of Medicine and in the library of the Medical College of Virginia. Individual exhibits will include old and modern sick rooms and operating rooms, photographs of Richmond physicians, old and modern instruments, medical books used in Virginia, medical photography and illustrations. Richmond hospitals and clinics will have booths to show their work and development, and the college itself will have several booths demonstrating its history and its work. The exhibits will open May 15 and continue through September.

GENERAL

Plans to Redraft Pharmacy Laws.—Plans for drafting a modern pharmacy law were announced after a meeting in Washington, January 17, of a committee appointed for the purpose at the annual meeting of the American Pharmaceutical Association in 1936. The draft of the new law will be presented at the next meeting of the association in New York in August. Officers of the state associations and state boards of pharmacy are being requested to give the committee the benefit of suggestions. The committee also announces that it will be pleased to confer with any state that is attempting to amend or rewrite its pharmacy law. The committee has the following members: R. L. Swain, Baltimore, chairman; H. C. Christensen, Chicago; R. C. Wilson, Athens, Ga.; Robert P. Fishel, Trenton, N. J.; A. D. Baker, Denver, and H. V. DeHaven, West Chester, Pa.

American Pediatric Society.—The forty-ninth annual meeting of the American Pediatric Society will be held at The Homestead, Hot Springs, Va., April 29-May 1, under the presidency of Dr. Henry F. Helmholz, Rochester, Minn. The speakers will include:

- Dr. Herman Yannet, New Haven, Conn., Effect of Hyperthermia on Distribution of Water and Electrolyte in Brain, Liver and Muscle.
- Ann S. Minot, Ph.D., Nashville, Tenn., Factors Influencing the Disposition of Fluids Given Intravenously.
- Drs. John A. Bigler, Highland Park, Ill., Laurie M. Hardy and Harry V. Scott, Chicago, Cryptorchism Treated with Gonadotropic Hormone, with Report of 100 Cases.
- Drs. Albert Graeme Mitchell and Josef Warkany, Cincinnati, Ohio, Relation of Endocrine Disturbances to Certain Heredodegenerative Symptoms.
- Dr. Randolph K. Byers, Boston, Tonic Neck Reflexes in Children, Considered from a Prognostic Standpoint.
- Dr. Waldo E. Nelson, Cincinnati, Possibility of Sensitization to Tuberculin.
- Drs. Mitchell I. Rubin and Milton Rapoport, Philadelphia, Cardiac Complications of Acute Hemorrhagic Nephritis.
- Dr. Arthur F. Abt and Chester J. Farmer, M.A., Chicago, Cevitamic Acid Content of Blood Plasma.

Meetings on Industrial Medicine in Detroit.—The Midwest Conference on Occupational Diseases will be held in Detroit, May 3-5, and will be followed by the annual meeting of the American Association of Industrial Physicians and Surgeons, May 6-7. Both will meet at the Hotel Statler. Subjects of the sessions of the conference will be pulmonary diseases in industry, industrial hygiene engineering methods, industrial dermatoses, occupational diseases and the practitioner of medicine. Among the speakers at these sessions will be:

- Dr. Emery R. Hayhurst, Columbus, Ohio, Industry as a Source of Disease.
- Dr. Andrew R. Riddell, Toronto, Ont., Industrial Tuberculosis.
- Dr. Marion B. Sulzberger, New York, Eczematous Dermatoses of Occupational Nature, with Special Reference to Proof of Occupational Origin.
- Dr. Robert T. Legge, Berkeley, Calif., Occupational Diseases and the General Practice of Medicine.

At the meeting of the American Association of Industrial Physicians and Surgeons, of which Dr. Robert P. Knapp, South Manchester, Conn., is president, the speakers will include:

- Dr. James A. Britton, Chicago, Compensation for Occupational Diseases.
- Dr. John J. Moorhead, New York, Trends in Industrial Surgery.
- Dr. Rosco G. Leland, director, Bureau of Medical Economics, Chicago, Economics and Ethics of Medicine.
- Dr. Plinn F. Morse, Detroit, Medicolegal Aspects of Sudden Deaths in Industry.

There will be round table discussions on industrial hygiene, led by Dr. Royd R. Sayers of the U. S. Public Health Service, Washington, D. C., and on industrial medicine and surgery, led by Dr. Otto P. Geier, Cincinnati. The annual banquet will be held Thursday evening, May 6, with Dr. Loyal A. Shoudy, Bethlehem, Pa., as toastmaster.

Winners in National Safety Contest.—New York City won first prize in the fifth annual traffic safety contest conducted by the National Safety Council for the calendar year 1936. In the contest were 1,013 cities. New York was also

first in the group of cities of populations larger than 500,000; Milwaukee was the winner in this group in 1935. First places in other population groups were as follows: Kansas City, Mo., cities from 250,000 to 500,000; Omaha, cities from 100,000 to 250,000; Jackson, Mich., cities from 50,000 to 100,000; West New York, N. J., cities from 25,000 to 50,000, and Wilmette, Ill., cities from 10,000 to 25,000. The judges named a special honor roll of 139 cities that had passed the year without a single traffic fatality. West New York was the largest of these. New York had 838 traffic accident deaths, 122 per cent lower than its 1935 total of 954 and 17 per cent lower than the average total for the three preceding years. Awards in this contest are made with consideration of various factors besides reduction of death rate, such as completeness in accident reporting, maintaining a permanent record of accidents, safe traffic planning and construction, effectiveness of traffic law enforcement, development of child safety and public safety education programs.

Federation of Societies for Experimental Biology.—The annual meeting of the Federation of American Societies for Experimental Biology will be held in Memphis, Tenn., April 21-24, under the auspices of the University of Tennessee School of Medicine and with headquarters at the Hotel Peabody. The federation is made up of four societies: the American Physiological Society, the American Society of Biological Chemists, the American Society for Pharmacology and Experimental Therapeutics and the American Society for Experimental Pathology. The first morning of the convention will be devoted to a joint meeting of all four groups with the following speakers:

- Dr. Hallowell Davis, Boston, Electro-Encephalograms and Their Interpretation.
- William C. Rose, Ph.D., Urbana, Ill., Further Experiments on the Nutritive Significance of the Amino Acids.
- Dr. Velyien E. Henderson, Toronto, Ont., Humoral Transmission of Nerve Impulses.
- Dr. Leo Loeb, St. Louis, The Biochemical Basis of Individuality.

The physiology program includes section meetings on endocrinology and metabolism, the central nervous system, carbohydrate metabolism, circulation and respiration, the kidney, nerve and general physiology, and a special symposium on coagulation of the blood. A few of the speakers are:

- Dr. Louis N. Katz and S. Rodbard, Chicago, The Role of the Liver in Regulating the Distribution and Rate of the Blood Flow.
- Dr. Charles H. Best, Arthur Charles, Ph.D., and Campbell Cowan, Toronto, Ont., The Administration of Heparin.
- Dr. Herbert S. Gasser, New York, Responses of Nerve to Two Trains of Rhythmic Stimuli.
- Dr. James B. Collip, Hans Selye and A. Neufeld, Montreal, Experimental Diabetes in the Monkey.

Among many speakers on the biochemistry program will be: Leroy S. Palmer, Ph.D., Minneapolis, Biological Assay of Vitamin E; Application to Wheat Germ and Wheat Germ Oil. Alfred Chanutin, Ph.D., and Stephan Ludewig, Ph.D., University, Va., Blood Plasma Proteins in Part. Dr. Frederic W. Schlutz and Minago, Influence of Kidney Secretion upon the Chloride and Base of the Dog During Exercise.

Dr. Rudolf Schoenheimer, New York, Studies in the Intermediate Metabolism of the Fatty Acids with Deuterium as an Indicator.

Papers to be read at the meeting of pharmacologists will include:

- Dr. Sanford M. Rosenthal and Hugo Bauer, U. S. Public Health Service, Chemotherapy of Bacterial Infections with Sulfonamide Compounds.
- Dr. Carl A. Dragstedt and Franklin B. Mead, M.S., Chicago, Further Observations on Peptone Shock.
- Dr. Nathan B. Eddy, Ann Arbor, Mich., Analgesic and Other Effects of Some Carbazoles.
- Dr. Willis M. Fowler and Adelaide P. Barer, Ph.D., Iowa City, Retention and Utilization of Orally Administered Iron.

Addressing the society of pathologists will be the following, among others:

- Drs. Charles A. Doan and Carl V. Moore, Columbus, Ohio, Correlation of Serum Iron, Bone Marrow and Blood Cell Changes Following Specific Therapy in the Macrocytic Anemias.
- Dr. Jesse L. Bollman, Dr. Frank C. Mann and Eunice Flock, Rochester, Minn., Factors Influencing the Fatty Condition of the Liver Produced by Alcohol and a Diet Rich in Fat.
- Forrest D. McCrea, Ph.D., and Harold M. Horack, Durham, N. C., The Effect of Artificial Fever on Experimental Rabies.

The afternoon of Friday, April 23, will be devoted to demonstrations at the university. The annual smoker will be held Thursday evening and the annual dinner Friday evening at the Peabody.

FOREIGN

Congress on Hematology.—An International Congress on Hematology will be held in Münster and Pymont, Germany, May 8-15, with Dr. Viktor Schilling, professor of internal medicine at the University of Münster, as chairman. Dr. Schilling has announced that interested hematologists from the United States will be welcomed at the congress.

Toxin Formation in Burns

Extensive burns produce systemic disturbances of which the causation is not well understood. W. C. Wilson, J. S. Jeffrey, A. N. Roxburgh and C. P. Stewart, of the department of surgery of the University of Edinburgh, have made an important investigation, which is reported in the *British Journal of Surgery*. They have clearly shown that toxin is generated in the burned tissues. The stage of acute toxemia begins between six and fifty hours after injury and not infrequently proves fatal about seventy hours after the burn. Clinical and pathologic studies strongly suggest the formation of toxin or toxins in the burned tissue and absorption into the circulation. There is also some evidence from experiments on animals. Recently, however, this view has been questioned.

As long ago as 1876, Avdakoff reported that the blood of a burned animal was toxic to healthy animals. In 1905 Pfeiffer published reports of experiments showing that the urine and blood serum of burned rabbits was toxic. But American experimenters—Underhill and Kapsinow—could discover no significant difference in action between extracts of burned skin and extracts of normal skin or between blood from burned animals and blood from normal animals. The Edinburgh investigators therefore decided that proof of the toxin theory was required. They made an incision in the middle line of the abdomen of rabbits under ether anesthesia, dissected up skin with subjacent platysma muscle as two lateral flaps, applied heat by diathermy to the deep surface of the flaps, and closed the incision. The animals subsequently showed no untoward symptoms. After varying intervals the edema fluid that accumulated was collected and injected into the ear vein of rabbits. Edema fluid removed four hours after the injury was always innocuous. Fluid removed at longer intervals was more and more toxic and at forty-eight hours highly toxic, killing forty of forty-four rabbits. Sometimes convulsions and death supervened within a few seconds of injecting from 3 to 5 cc. In other cases after several minutes muscular weakness, labored respiration, increased heart rate, pallor of the ears and hydriasis developed. The weakness increased, the temperature fell and death occurred after from one to five hours, sometimes preceded by muscular twitchings or general convulsions. Subcutaneous injections were also toxic but the lethal dose was larger. The fluid was found sterile; therefore bacteria played no part in the result. Autolysis of the injured tissue was evidently the mechanism of toxin production. In the fatal cases, fatty degeneration of the liver cells was found.

Precautions Against Air Raids

Precautions against air raids have now become such a topic that they are discussed almost daily in the press. Mr. Geoffrey Lloyd, undersecretary to the Home Office, stated in a reply to a question in the House of Commons that during an air raid the public should as far as possible remain indoors, in a part of their home or place of work that has been adapted as a refuge in accordance with instructions which will be issued. The question of provision of refuges for persons caught in the street when a raid is imminent is under consideration. It is considered that if ordinary safeguards are employed for these, the installation of a filtration plant will not be necessary. Arrangements will be made for detection of poison gas as part of the organization. Every effort will be made to warn the public of the presence of gas, which they may not be able to detect themselves.

A specimen gas-proof room has been fitted up in London by the special air raids precaution committee of the corporation of the city in conjunction with the St. John Ambulance Brigade. The room is open for public inspection daily and experts lecture at frequent intervals on precautions against poison gas. The committee has also issued a pamphlet on the preparation of a refuge room. In the list of material recommended for the furnishing is a wireless set for the information and entertainment of the occupants. The specimen room is hung with blankets tacked to the lintel with wooden strips, and the joints in the window are protected with strips of felt. It is shown how, by pasting three sheets of cellophane inside a window pane, the glass is not likely to splinter if exposed to the concussion of bombs in the street. Cracks in walls and floorboards, mouse holes and so on may be filled with paper soaked in water and squeezed to pulp. A broken window may be made gas proof by nailing an old carpet across the frame. A more elaborate precaution exhibited is a wooden frame, the exact size of the window, covered with wire netting over which a blanket is stretched.

Similar precautions are being taken all over the country. At Eastbourne, a town on the east coast and therefore exposed to raids from the continent, a government expert lectured to a large audience presided over by the chairman of the Air Precautions Committee, who appealed for 650 volunteers to staff first aid posts. All the police have been trained and the second police reserve is now being trained. The town has been divided into nineteen sections, each controlled by a warden elected from among the volunteers. It is proposed to set up first aid posts, so that no one need walk more than a mile when contaminated with gas. All the civilian air raid training is entirely voluntary in England, whereas in Germany it is compulsory, as also is the provision of bomb-proof shelters. Mr. Wilmot, the government expert, said that nothing less than 15 or 20 feet of reinforced concrete would stop a direct hit by a high explosive, and the cost of shelters for the population was prohibitive. But every one could prepare splinter-proof rooms in his own home. In every home, shop and business place there should be gas-proof shelters. A corps of persons known as "gas detectors" is being organized throughout the country whose duty will be to detect gas and inform the authorities.

The government has decided that 300,000 volunteers are to be recruited as wardens, whose duty will be to advise residents on the officially recommended precautions against air raids, to assist in the distribution of civilian respirators, and to help the public both during and after an air raid. It is proposed that every district, singly or in cooperation with its neighbors and in consultation with the police, shall arrange for the organization and training of the air raid wardens. Wardens will operate from fixed posts, of which there will be one for every 500 inhabitants in residential districts and one to every quarter of a mile in industrial and business areas. The Air Raids Precautions Department has asked societies of experts in chemistry to help in the organization of a gas-detection service, which will be part of the local authorities' air raids precautions service. Their duties would be to proceed to an area where poison gas was reported, to decide whether gas was present, and, if so, which gas, and to advise on the extent of the danger.

A Forty-Eight Hour Week for Nurses

The nursing profession is the latest to be affected by the general tendency to reduce hours of work. Sir Kingsley Wood, minister of health, visited the Victoria Memorial Jewish Hospital, Manchester, to lay the foundation stone of a new nurses' home, which enables the present staff of fifty-one nurses to be increased by fifteen or twenty, and thus to be inaugurated, for the first time in Great Britain, a forty-eight hour week for nurses. The minister commended the hospital for the steps it had taken in the interest of nurses. Hours of work were a

difficult matter because the interests of the patient did not always permit of rigid adherence to a limit. On the other hand, exhausted nurses could not carry out their arduous duties. Exhausting hours were particularly deplorable for probationers, because they interfered with study and training. In hospitals which he had recently visited there was a decrease in the recruitment of nurses, and the conditions he had mentioned were calculated to have a deterrent effect. He therefore greatly valued the example set by the management of the Victoria Memorial Jewish Hospital in instituting a forty-eight hour week for nurses. He was glad to think that it had been largely inspired by a race whom Britons greatly valued in this country and whom we always desired to have with us. The hospital had never discriminated between suffering people on the basis of either creed or race.

Social Insurance and the Mortality Rate

In a recent letter (*THE JOURNAL* February 13, p. 568) an article by Dr. Phillip Dally on sickness insurance and mortality, which appeared in the Dec. 2, 1936, issue of the *Presse médicale*, was cited. The author stated that the mortality rate was lower in countries in which no social insurance laws were in effect. A criticism by Dr. Alexandre Roubakaine of this article and a reply by Dr. Dally appeared in the February 13 issue of the same journal. Dr. Roubakaine stated that sickness insurance applies only to treatment of those who are ill and that only minimal efforts had been made in any country in which such insurance exists, in the direction of prophylaxis; hence sickness insurance can have no influence on the mortality rate. The statistics quoted by Dr. Dally with regard to the mortality rate from diphtheria being less in non-socially insured countries had been correct but erroneously interpreted, because immunization against diphtheria had not been carried out in such countries; therefore one must bear this in mind when a failure to decrease the mortality in socially insured countries is quoted. For example, in non-socially insured countries, such as the United States and Canada, millions of children had been immunized since 1926. Roubakaine also disagrees with Dr. Dally on the statistics of mortality in general being lower in non-socially insured countries, citing first the latter group as follows: In the Union of South Africa and Canada the mortality has remained unchanged from 1921 to 1933. In Argentina there has been a drop of 21 per cent from 1921 to 1933. In the United States, Netherlands and New Zealand the drop in the mortality rate from 1905 to 1933 has been respectively 33, 30 and 22 per cent. In countries in which social insurance exists, in Germany the mortality between 1905 and 1933 has decreased 33 per cent, in England during the same interval 18 per cent, and in Chile 17 per cent. Thus one must conclude that the drop in mortality rate has taken place in the same rhythm or perhaps at a slightly accelerated rhythm in socially insured as compared to non-socially insured countries. Certain of the latter group (Canada, the United States, New Zealand) had a much lower mortality twenty-five years ago than England and Germany. Even the mortality rates from tuberculosis and children's diseases which were quoted by Dr. Dally as being lower in non-socially insured countries at the present time are wrong according to Roubakaine, because they were lower twenty-five years ago in these than in socially insured countries. On the contrary, the lowering of the mortality rate in Germany and England (where social insurance exists) has been more rapid than in non-socially insured countries such as the United States, Canada and Australia. In closing his criticism of Dr. Dally's statistics, Roubakaine again reminds one of his belief that social insurance bears no relation to the problem of mortality, because so little is being done by countries in which it exists, toward prophylaxis

of disease. The object of social insurance, he again repeats, is to care for those already sick and not prevent those in good health from becoming ill.

Dr. Dally's reply was that Dr. Roubakaine maintains that social insurance is "equivalent to a system of treatment at reduced rates." Social insurance places salaried workers in the same category as indigents, for whom a system of relief aid when sick has existed for many years in all civilized countries. In France a third of the population is considered "feeble from an economic point of view," a milder form of expression for indigent. The medical profession does not balk at giving free service of the best kind to a small portion of the population when they are really indigent. But, in a system like that which the present social insurance law has brought about, which affects nearly the entire number of those who are ill, can one hope to give the same medical high grade care at cheap rates? If social insurance cannot modify the mortality rate as Dr. Roubakaine asserts, of what benefit to a country can it be? A better system than social insurance is to place every possible method of diagnosis, no matter how costly, at the disposition of the medical profession, the expenses being borne by the community. Medical men will then render the best services possible to the sick. For political reasons, another course has been taken here toward state medicine, thus depriving medicine of its therapeutic forces, which embrace the independence of the medical profession and a free choice of physician by the sick. "The statistics I have quoted prove that social insurance is a failure. I agree that prevention is the first duty of the state and if the social insurance organizations would do so, they would not exist in vain. A large sum of money, now sequestered, at least in France, ought to be devoted to prevention."

Definition of Proposed Public Health Centers

Since his appointment in June 1936 the present minister of public health, M. Henri Sellier, has proposed to establish "health centers" in every department of France. His object is a laudable one, to enable every citizen, even if unable to pay, to enjoy all the advantages of modern medicine. There has been much discussion as to what these health centers would do that is not being done by existing organizations. It will be recalled that reference has been made in recent letters to the offer of the Federation of Medical Syndicates, representing nearly every physician in France, to take complete charge of the medical aspects of such centers. In order to calm the rising storm of opposition to the establishment of health centers, which are regarded by many as an attempt to make every physician a state official, the assistant minister of public health, Dr. R. H. Hazemann, attempted to allay all fears by giving a definition of the health center at the recent meeting of the Congress on Hygiene held at Paris last October. He stated that there had never existed any plan by which state centers for treating patients would be established. The center was not a hospital in any sense of the word. There would be no wards, physicians or nurses. The department of public health only wishes to coordinate and centralize the present dispensaries and social service work. Although fundamentally a medical organization, the chief objective of the department is preventive and social medicine. There is much avoidable overlapping of the work of different public health agencies, which results in less efficient service than would be possible if better coordination existed. Wherever a given region does not possess dispensary service, one will be established. The functions of a health center will include surveillance of maternity cases and the new-born, school inspection, antituberculosis service, antisyphilitic service, detection of cancer and rheumatism cases and health examinations in addition to those at the school periods, to be made at the ages of 15 to 20 years (especially for early signs of tuberculosis) and between 45 and 50 years (for cardiorenal disease and cancer). The examinations are to be made by local practitioners, selected

by the departmental (medical) syndicate. The services are to be remunerated on the basis of a collective contract between the syndicate and the public health authorities. These preventive centers are to be aided by a well trained staff of visiting nurses. The health center, so far as its medical services are concerned, will be under the supervision of a full time physician. In each of the eighty-six departments a coordination committee is to be appointed, made up of delegates of existing public medical administrative organizations, delegates of existing endowed institutions and delegates from the medical syndicates, social insurance bureaus and labor unions.

Exteriorization of an Infected Uterus in Cesarean Section

At the January 20 meeting of the Académie de chirurgie, a paper was read by Louis Portes, associate professor of obstetrics at the Paris Faculté de médecine, on the end results of his method of exteriorization of the uterus in certain cases of cesarean section. He stated that the greatest obstacle encountered in obstetric surgery by the abdominal route was that associated with possible infection of the uterine cavity. When a cesarean section is deemed unavoidable at a late stage of labor, in the presence of an open amniotic sac and the likelihood that vaginal infection has extended to the uterine cavity, conservative cesarean operations, which have only a minimal mortality rate under normal conditions, become procedures accompanied by grave risks. Death of the mother can result from inoculation of the peritoneum with the septic intra-uterine contents, either immediately at the time of operation despite every possible precaution or after eight or ten days as the result of the breaking down of the infected wound in the uterine wall.

Portes has employed, since 1923, a technic (which is well illustrated in the Académie de chirurgie bulletin of January 20) in which the uterus, tubes and ovaries are well isolated by gauze packs from the other abdominal viscera. The uterus is then opened in the usual manner and, following delivery of its contents, the uterine incision is closed; but instead of the uterus, tubes and ovaries being replaced they are exteriorized by closure of the abdominal (parietal) incision tightly around the uterus at as low a level as possible. About three weeks later, the uterine incision can be made more resistant by secondary suture. The uterus, tubes and ovaries can then be replaced into the abdominal cavity about the thirty-fourth day.

Portes communicated the end result of the first case in which this technic was employed, in 1923. The patient, 21 years of age, had a normal delivery in 1922. Dr. Portes was called during the second pregnancy in 1923, when the bag of waters had been ruptured for 130 hours, the temperature being 100 F. and the pulse 160. The amniotic fluid had a fetid odor; hence the necessity of immediate evacuation of the uterus was indicated. Portes had at first contemplated performing a cesarean operation followed by hysterectomy, but he feared to replace the infected uterine stump in the abdominal cavity and decided to exteriorize following delivery of the fetus. His fear of a breaking down of the uterine scar was justified by the fact that this took place a few days after exteriorization of the uterus. The patient left the hospital fifty-one days after the operation.

Professor Portes was able to follow this first case during three subsequent pregnancies. In 1930 a second cesarean section was necessary on account of a contracted pelvis. Microscopic study of the scar of the first incision revealed that a normal reparative process had taken place. In 1934 a fourth pregnancy necessitated version and forceps delivery. In 1935 a fifth pregnancy ended in abortion.

Since this first exteriorization operation, Professor Portes has employed the same technic in a number of other cases with satisfactory results.

BERLIN

(From Our Regular Correspondent)

March 15, 1937.

New Aspects of Some Medical Questions and Nature Medicine

According to an announcement by the medical führer, Dr. Wagner, every new doctor is expected to engage in general practice for one year before entering a special field.

With the new year a "physicians' Sunday rest period" was inaugurated for the insurance physicians of Bavaria. It will apply to all Sundays and holidays. The rest period begins at 7 p. m. on the previous day and lasts till 7 a. m. on the next week day. In order to guarantee medical attention in emergencies a Sunday medical service has been set up based on mutual agreement among the insurance physicians as to which of them will serve on a given day.

The question of whether or not the sale of a medical practice in case of death, for example, or change of location, is compatible with professional ethics has been much controverted. It has been the general opinion of the more ethical members of the profession that a medical practice is far too personal and too much based on the confidence of the individual patient to be made the object of a commercial transaction. The highest Prussian tribunal, the Kammergericht of Berlin, has likewise recently gone on record against the sale of a medical practice. Conversely, the highest tribunal in Germany, the Reichsgericht, has decided that the compensated transfer of a practice from one physician to another in no way constitutes a breach of professional ethics. This is a juridical decision of the first importance and as such it is most worthy of note. Only under particular circumstances could such a transaction appear to be ethically reprehensible as, for example, if the buyer of the practice was compelled by the conditions of the contract to exploit his profession for pecuniary ends and thus disregard the supreme duty of every doctor; namely, service to the health of the individual patient and of the community.

The consultation of Jewish physicians, even those still permitted to practice medicine in Germany, by holders of public office, that is, officials, employees and others, has been made impossible by a decree of the present national minister of finance. Public servants can thus no longer receive monetary sick benefits and so-called emergency aids to cover indebtedness to any Jewish physician, dentist, pharmacist, lay practitioner, institution for the sick and convalescent, lying-in institution or undertaking establishment. Exception is made only in cases of a life and death emergency. Also in future the testimony of Jewish physicians with regard to the permanent or temporary disability of an insured person will no longer be considered competent. These provisions apply to all public servants and their dependents.

The National Organization for a New German Medicine, founded at Nuremberg in May 1935 (THE JOURNAL, April 11, 1936, p. 1327) has been dissolved. This national organization received a great deal of publicity at the time of its joint convention with the German Society of Internal Medicine (THE JOURNAL, Aug. 15, 1936, p. 514); elsewhere, however, it expended all its energies in the interests of Nature Medicine. The dissolution was made on the basis of the National Statute of Physicians at present in force, since according to this law all scientific organizations are under control of the National Health Bureau. The possibility for the national organization to remain in its old form therewith vanished. The functions and the aims remain, however, as the medical führer, Dr. Wagner, explained and he declares furthermore that already great sections of the German medical profession believe in the fundamentals of a new German medicine. The nature cure methods "so reprehensibly neglected in the past" have come to be included among the graduate studies of physicians. In future

the scientific building up of nature cure methods will be carried on under the president of the National Health Bureau. The ultimate educational objective, penetration of the entire medical profession by the new political ideology, will be carried forward by the National Socialist League of German Physicians under the leadership of Dr. Wagner himself.

As every one knows, persons without regular medical education are permitted to attend the sick in Germany. Such persons are known as *heilpraktiker* (lay practitioners). The Association of German *Heilpraktiker* has recently been recognized by the government and the Nazi party as the sole representative organization of the lay practitioners' group, and only members of this association are authorized to use the term "*heilpraktiker*." A person who does not belong to the association may perhaps call himself "*heilkundiger*" (healer) but never "*heilpraktiker*." A person who, being neither a licensed physician nor a *heilpraktiker*, attempts to treat disease is considered a quack.

In addition there is the National League of Chiropractors, with headquarters in Hamburg. These chiropractors have decided to establish a standard three year period of training. The chiropractors number among their activities the removal of corns and ingrowing toenails, and similar procedures, the manufacture of "foot appliances," the correction of plantar defects and the prescription of so-called hygienic footwear.

The question When should a healer refer his patient to a regular physician? is quite timely and important in view of the present state of toleration and recognition in Germany of uneducated healing practitioners, who in any other country would generally be regarded as charlatans. In this connection a recent opinion of the Supreme Court of Germany is significant. According to this opinion it is the duty of the untrained healer to refer the patient to a physician whenever the healer comes to realize after careful and conscientious attention and observation that more than his limited knowledge and skill is necessary for the treatment of the disease. The healer's responsibility is materially increased if the illness is serious and his own procedures have failed to produce a favorable response. If a healer has been asked by the patient or patient's relatives whether a physician should be called in to verify his capabilities and knowledge, the duty of referring the case to a physician becomes doubly incumbent on the healer.

In closing it might be mentioned that the Mazdaznan movement in all its ramifications has been dissolved and suppressed throughout Germany and its properties confiscated.

The Quality of the Mucosa

The investigations of the types of human physique carried on by the Tübingen school are a matter of common knowledge. A recent addition to these studies was a paper on the interrelation of physique and mucous membrane submitted by Dr. Schwarz in the Tübingen Medical Society.

In chronic catarrhal conditions of the nose, pharynx, larynx and middle ear, one finds during the interval between attacks that the mucosa is either thicker or thinner than the normal. Although paratypical influences are of course present, clinical observation has shown that individual variations in the quality of the mucous membrane existed prior to the onset of the disturbance. As the character of the mucosa is largely determined by that of the matrix (*tunica propria*) of the connective tissue, comparative examinations of the connective tissue of the embryonal mucosa of the middle ear were undertaken. It was observed that the cellular structure of the connective tissue possesses a developmental ability that differs with the individual person. It was further determined that the tendency to form fibrils within the connective tissue also presents individual variations. Since the matrix of the connective tissue is derived from the mesenchyma, that is, from the same germinal layer as the supporting and connective substances, an interrelation comes

to exist between the mucous membrane and the bodily physique. It was possible to demonstrate that the mucosa of asthenic persons is delicate, thin and little perfused with blood, whereas that of sthenic persons is thick, juicy and well perfused with blood. It was further ascertained that among persons whose mucosa is manifestly hyperplastic, as among patients who suffer from nasal polyposis, the sthenic (that is, muscular, pyknic) type predominates. On the other hand, if manifest atrophy of the mucous membrane is present, as in *ozena*, a great majority of the patients are of asthenic physique. A connection between the physical type and the quality of the mucosa may be safely assumed on the basis of these observations. Till now, however, this interrelation had not been recognized.

No More Nobel Prizes for Germans

As recently told in the daily press, the German government on January 30 forbade on political grounds the future acceptance of a Nobel prize by a German. As an alternative there has been established a "German National Prize for Art and Science," which will consist of about 100,000 marks, to be distributed annually among three deserving Germans.

It is interesting to note in this connection how many Germans have been awarded the Nobel prize, which has been distributed almost uninterruptedly since 1901. The Nobel prize for medicine and physiology has been awarded to seven Germans: Emil Adolf von Behring, Robert Koch, Paul Ehrlich, Albrecht Kossel, Otto Meyerhof, Otto Warburg and laterly to the zoologist Hans Spemann in 1935. The chemistry prize was received by fifteen Germans, the physics prize by twelve, the prize for literature by five and the peace prize by three.

This proud roster of men whose contributions to knowledge have been deemed worthy of the highest honor has now been brought to an end.

BELGIUM

The Twenty-Eighth Congress of Professional Medicine

The twenty-eighth Congress of Professional Medicine brought a large number of physicians from all parts of Belgium to Liège. In the opening address Minister of Health Emile Vandervelde promised that prompt consideration would be given the much debated question of an "*Ordre des médecins*" (council to regulate professional ethics). He himself advocates legislation that would safeguard professional ethics and at the same time in no way impair professional freedom. He also evinced the keenest interest in the dissemination of *cartes sanitaires* (personal health records carried by citizens).

Dr. Féron's report on the more extensive use of the *cartes sanitaires* and the reports on the proposed medical professional legislation by Professors Brèyre and Coppez and Dr. Daubresse-Morelle all gave rise to lively discussions, which occupied the delegates throughout Saturday afternoon and Sunday morning. At the close of these deliberations the following resolutions were unanimously adopted:

1. Preventive medicine. From the standpoint of professional secrecy, the organization of preventive medicine as effected by the *Fédération médicale belge* excludes all possibility of indiscretion and abuse and assures efficient and permanent coordination among the various medical social services for the benefit of the person who holds a *carte sanitaire*. Finally, it vouchsafes to every citizen a handy documentary record or balance sheet of his most precious possession, health. Any physician who wishes to see social medical service pledged to a cooperation with the rest of the medical profession, including the family practitioners, and who believes in the maintenance of an absolute professional secrecy, ought to participate in the campaign begun by the *Fédération médicale belge* within the domain of preventive medicine, on the basis of the program decided on by the Committee on Social Prophylaxis.

2. L'Ordre des médecins. The twenty-eighth Congress of Professional Medicine after having reconsidered and affirmed the urgent need for the creation in Belgium of a council to regulate exclusively the ethics of the medical profession, all financial and syndical considerations aside, demands the immediate creation and maintenance in activity by the executive council of the *Fédération médicale belge* of a permanent commission representative of the diverse opinions with regard to this question.

It will be the duty of this commission to attempt to formulate with the minimum of delay the first draft of a bill to regulate professional ethics, together with a summary of critical opinion. This bill in its final redaction will be introduced into parliament, and the commission will undertake in the course of the discussion incident to its eventual enactment to explain the objectives of the measure to both parliament and the general public. The commission will continue in existence until the legislation has been enacted.

THE CHEMOTHERAPY OF MALIGNANT TUMORS

Hans Auler of Berlin discussed the physicochemical bases of malignant tumors. After outlining various concepts that have enjoyed currency since the beginnings of the chemotherapeutic approach to cancer he discussed the fundamentals of this type of treatment and its prospects of development. The older concept is that therapeutic success depends not alone on the method of application but also on the affinity which a chemical substance may have for the cancerous cell, assuming that this substance is stored within the cancer cell and becomes active by accumulation. Direct action is, moreover, dependent on the vascularization of the tumor, a prime factor, since it is the circulatory system which must maintain the element hostile to the tumor within the diseased tissue. Auler makes macroscopic and microscopic demonstrations of the vascularization in malignant tumors and then studies the various ways in which substances employed in the chemotherapy of cancer may act. He described his personal experimentation with the effects of sodium desoxycholate and kindred substances derived from *Buforana* and *Digitalis purpurea*. He also discussed the interrelation of carbohydrate and cholesterol metabolism within the cancer patient.

Maisin and Pourbaix of Louvain discussed the organoprophylaxis of tar and benzopyrine cancers. They attempted chiefly an outline of the results of their own investigations carried on over the last three years. The principal fact elicited from these investigations was that the organs involved have at their disposal whole complexes of inhibitory and activating substances, the equilibrium of which influences the karyokinetic processes within the organs with particular reference to the differentiation of the latter. The proportions of activating and inhibitory substances is not the same in all organs: certain organs in a fresh condition contain an excess of activating substances over inhibitory substances and vice versa. The liver, when fresh, is an example of an organ in which activating substances predominate, and the brain is an example of the opposite sort for, if in a fresh state, it presents a preponderance of inhibitory substances. Nevertheless, from both the liver and the brain effective substances having the recessive property may be obtained; thus, an organ containing principally activating substances contains at the same time quite effective inhibitory substances. Activating substances may be extracted into distilled neutral or alkaline water, but similar substances will still remain within the pulp of the organ in question. The inhibitory substances are much more difficult to extract and above all to preserve than the activating substances. The authors outlined two methods of extraction, with ether or with heated alcohol. Once extracted, the activating substances as well as the inhibitory substances resist boiling. Exceptions are the inhibitory substances from the stomach. After the extraction by ether of the inhibitory substances, the dry pulp

of the organ is an activating mixture for tar cancer and benzopyrine cancer. Studies made of the desiccated stomach and of the same organ when boiled seem to indicate that the inhibitory substance can be a product of normal digestion. The authors asked whether the inhibitory substances are lysins or substances of differentiation. They believe that the production of activating substances and inhibitory substances forms part of a great process of oxidation-reduction which regulates fundamentally all tumoral metabolism and which lies at the base of antineoplastic immunity. It may be that the catalyzers of oxidation such as the peroxides play an important part in the production of these substances. The authors base this hypothesis on recent investigations of various syntheses of organic peroxides.

Care of the Maimed and Crippled

An interesting comparative study by Dr. Charles Dam, published in the July issue of the *Revue du travail*, concerns legislation aimed to protect the crippled. The following is a summary of Dr. Dam's conclusions:

1. Since the problem of aid for crippled persons is essentially the problem of aid for crippled children, it is necessary that the legal and administrative set up be such that: (a) the census and the follow up of crippled children will be assured; (b) these children will receive the most complete and skilful attention possible; (c) the organic laws of elementary education will permit all crippled children to receive proper instruction, it being understood that a child may continue his school work while he is undergoing medical treatment; (d) special classes may be organized in the public schools and indispensable special schools may be created by public authorities and private foundations; these schools will contain (1) complete clinical and consulting services, (2) kindergarten classes and classes in elementary instruction through all the grades and (3) vocational schools to which adults capable of receiving instruction will also be admitted.

2. It should be provided by law that a certain proportion of crippled persons be employed by various benevolent organizations at various mechanical tasks, as is customary in many other countries.

3. Workshops for the crippled should be established by means of special subsidies.

4. Local regulations should favor the more seriously afflicted cripples by reserving for them so far as it is practicable the care of newspaper stands and jobs in the minor trades.

5. There exists a most urgent need for social insurance legislation.

6. There should be more exact correlation of the various laws which regulate aid for the crippled, the blind, and the deaf-mutes. The problem of psychic abnormalities also requires more adequate legal regulation.

7. It would be desirable to enact special legislation for the deaf-mutes and the blind, since pedotechnical conditions among these groups will differ greatly from those of maimed and crippled persons.

It would be highly gratifying to see the Rotary Club's Association for the protection of crippled children expand its present activities (promotion of the education and treatment of crippled children) to include the sponsorship of trained crippled persons; that is, to continue to supervise and aid such persons in adulthood. By rendering this additional service the association would be performing one of the most necessary duties in the sphere of protection for the crippled. Nothing short of a comprehensive approach to the problem by a private agency will produce the optimal results.

Postvaccinal Encephalitis

Drs. Van den Branden and Nélis have published a study of postvaccinal encephalitis in the *Bruxelles médical*. They point out its rarity in Belgium as compared with other countries. The manifestations are apparently uninfluenced by the seasons.

The virus is unknown. The authors describe the lesions in the brain and spinal cord. The best prophylaxis is vaccination in early life. The treatment indicated is intravenous administration of serum either from persons who have recently undergone successful antivariolic vaccination or from an immunized horse.

Prize for Cancer Research Activities

The Belgian Mining Association of Upper Katanga (Belgian Kongo) has awarded a prize to Prof. E. L. Kennaway, one of its scientific staff, and to Prof. J. W. Cook of the Royal Cancer Hospital, London, for their work in cancer research.

The award was made at the second Cancer Congress, held at Brussels late in September. The prize consisted of 50,000 Belgian francs and 50 mg. of radium.

Chronic Nephritis and Lead Poisoning in Queensland

A study of mortality causes in Queensland shows that a large number of people die at an early age from kidney disease. Sometimes several members of one family are affected. The incidence of lead poisoning among children in Queensland is high. It must be understood that in Queensland, owing to the tropical sun, the paint on exposed surfaces powders readily, so that there is an abundance of lead carbonate available to be picked up by youthful fingers.

Medical practitioners in Brisbane and other parts of Queensland have long held that chronic nephritis, terminating fatally in uremia, is more prevalent in that part of Australia than it is in other parts of the world. In 1929 D. G. Croll put this impression on a sound statistical basis by showing from the death returns of the ten year period 1917-1926 that 1,309 persons in 800,000 of the population died of chronic nephritis in Queensland before the age of 40, whereas in the other three states of the commonwealth the number was 436, 421 and 418. A graph of the deaths in the various age groups indicates clearly that a cause nonexistent or nonoperative in the other states was responsible for this strangely high mortality in Queensland, with its peak in the 20 to 29 age group. It fell to L. J. J. Nye of Brisbane to relate this mortality to chronic plumbism in "Chronic Nephritis and Lead Poisoning," a work that may be regarded as the most important contribution of Queensland to medical knowledge since T. L. Bancroft discovered the adult filarial worm there fifty-eight years ago.

Cases of wrist-drop and foot-drop were first described in Queensland children in 1892. In 1897 J. L. Gibson began to encounter weakness of the external recti combined with papilledema, which he regarded as an early and therefore important sign of lead poisoning; in fifteen years he saw fifty-four cases. In seeking a cause for the plumbism, Nye was led to examine closely the habits of children. In Queensland the verandas of houses are commonly built with railings of wood, which, especially in the neighborhood of towns, are usually painted with white lead paint. In that semitropical climate the sun soon converts this paint into a powdery substance which rubs off easily on the hands, and this has been found to be a soluble carbonate of lead. In the summer young children spend a large part of their time on the verandas, and the younger members of the families affected are generally in the habit of biting their nails or sucking their fingers. Among children a local pastime was discovered which consisted in licking the rain drops from the veranda railings. More recently S. F. McDonald, going over the same ground, accepted the "paint-fingers-mouth" theory of causation as the best working hypothesis. As a rule the patient first comes under medical observation early in adolescence, the history being that for years

the child has not been as well as other children. In later stages this lassitude increases, and anemia, vomiting, failing vision and often epistaxis occur. Elevation of blood pressure is invariably present and is accompanied by hypertrophy of the heart. Occasionally cerebral hemorrhage resulting in hemiplegia has been observed. Retinal vascular changes, with engorgement of veins, hemorrhages, exudate and choked disks, are commonly seen. Edema is inconspicuous, and renal failure ending in uremia is the usual conclusion.

A federal investigation published in 1932 upheld the contention that kidney disease in young persons in Queensland is extraordinarily prevalent. It reached the tentative conclusion that the chronic nephritis common in Queensland arises, as elsewhere, as a result of many factors productive of kidney damage, including principally familial weakness of the kidney fabric, damage produced by congenital syphilis, and conditions set up as the result of the acute or prolonged action of toxins derived from pathogenic organisms. In Brisbane, in cases in which such predispositions exist, the concurrent ingestion of infinitesimal doses of lead from an undetermined source appears in a proportion of cases to precipitate a fatal issue many years earlier than would otherwise be the case, weeding out the great mass of patients with chronic nephritis before they attain the age of 40. Since whatever factor is operating in Brisbane appears to be operative also in several other cities of the Brisbane type, the possibility of lead poisoning being a factor in these areas, though it does not figure in hospital records, cannot be entirely discounted but must be investigated before conclusions can be accepted as final. The work on which these tentative conclusions are based is included in the full report submitted to the director general of health in Canberra. Nye replied to the conclusions of the official inquiry by showing that after a careful review of the statistical, clinical, environmental and experimental evidence that has been collected in the federal report and in his work it must be admitted that lead poisoning in childhood is at least one factor which is responsible for the high rate of mortality from chronic nephritis in Queensland—a rate, however, which happily now shows some signs of abating. The amount of positive evidence incriminating lead paint is indeed so overwhelming that it seems almost perverse to insist on a further search for other causes before taking preventive measures against poisoning. Nye's work emphatically teaches the lesson of the damaging effects of lead on young tissue and strengthens the demand that lead should be forbidden in paint, especially on surfaces such as veranda railings and gates to which children have ready access.

Marriages

JEROME ENGEL, Ravena, N. Y., to Miss Pauline Barthman Feder of East Orange, N. J., in Albany, N. Y., March 17.

NEWSOM P. BATTLE to DR. MARGARET ELIZABETH WHITE, both of Rocky Mount, N. C., in Detroit, January 2.

IRWIN W. BARRETT, Clarksdale, Miss., to DR. ALLIE M. ARRINGTON of Richton, February 28.

MAXCY WILBUR HOOK to Miss Mary Wilson Meiklejohn, both of Cheraw, S. C., March 18.

JOSEPH G. GUSTAFSON, Moline, Ill., to Miss Hilda Kosman of Wausau, Wis., Sept. 21, 1936.

FRANCIS RAMON BURKE to Miss Mary Stuart Merritt, both of Quincy, Mass., January 23.

FREDERIC L. BAER to Miss Jeanne Lois Traugott, both of Indianapolis, Dec. 24, 1936.

CLARENCE S. COSTIGAN, Moline, Ill., to Miss Frances Ostewig of Chicago, Nov. 26, 1936.

JUDD R. BREAKSTONE to Miss Gertrude Stern, both of Chicago, January 29.

GUY E. DORE to Miss Doris Elizabeth Ladd, both of Guilford, Maine, April 3.

Deaths

Theobald Mathew Marie Flynn, Eric, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1911; member of the Medical Society of the State of Pennsylvania; fellow of the American College of Surgeons; consulting obstetrician, gynecologist and staff surgeon to St. Vincent's Hospital; member, associate staff, Hamot Hospital; consulting gynecologist to St. Joseph's Orphan Asylum; assistant surgeon, Pennsylvania Railroad; aged 61; died, February 6, of carcinoma of the prostate.

Forrest Kendall Anderson, Sonyea, N. Y.; Baylor University College of Medicine, Dallas, Texas, 1929; member of the Medical Society of the State of New York; member of the consulting staff, Craig Colony, Sonyea, and member of the junior dermatologic staff of the Rochester General Hospital, outpatient department; formerly member of the staff of the state department of health; aged 31; died, February 13, of teratoma with pulmonary metastases.

Cornelius Doremus Van Wagenen * New York; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1893; member of the city health department in 1897; assistant otologic surgeon to the Manhattan Eye, Ear and Throat Hospital; attending otolaryngologist to the Seton Hospital, 1904-1914; aged 71, died, March 5, in the Harbor Hospital, of arteriosclerosis and hypertension.

George Mossman, Gardner, Mass.; University of Vermont College of Medicine, Burlington, 1914; member of the Massachusetts Medical Society; fellow of the American College of Surgeons; served during the World War; on the staffs of the Henry Heywood Memorial Hospital and the Gardner State Hospital; school physician of Westminster; aged 47; died, February 7, of influenza.

Simon Tannenbaum * New York; Bellevue Hospital Medical College, New York, 1896; medical director of the Sydenham Hospital; formerly superintendent of the Beth David Hospital; at one time served as the director of the medical activities in Palestine of Hadassah, and was director of the Hadassah Hospital; aged 64; died, March 1, of arteriosclerosis.

Charles Beaver Mack, Boston; Jefferson Medical College of Philadelphia, 1910; district health officer in the Boston metropolitan area; medical director of the Episcopal Eye, Ear and Throat Hospital, Washington, D. C., 1922-1927; served during the World War; aged 50; died suddenly, January 23, of coronary thrombosis and hypertension.

Harris Fenton Brownlee, Danbury, Conn.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1888; member of the Connecticut State Medical Society; fellow of the American College of Surgeons; on the staff of the Danbury Hospital; aged 70; died, February 24, of cerebral arteriosclerosis.

William C. Dixon, Greenville, Ill.; Beaumont Hospital Medical College, St. Louis, 1895; member of the Illinois State Medical Society; president of the Bond County Medical Society; and past president of the Vermilion County Medical Society; formerly health officer of Danville; aged 67; died, February 12, in the Barnes Hospital, St. Louis.

Thomas J. McArthur, Cordele, Ga.; Southern Medical College, Atlanta, 1894; member of the Medical Association of Georgia; past president of the state board of medical examiners and member of the state board of health; on the staff of the Cordele Sanatorium; aged 68; died suddenly, February 15, of heart disease.

Thomas Owen Maxwell, Austin, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1878; member of the State Medical Association of Texas; formerly superintendent of the Texas Training School for Defectives and Sanitarium for Mental and Nervous Diseases; aged 83; died, February 18.

Joel Isham Denman, Kansas City, Mo.; Beaumont Hospital Medical College, St. Louis, 1900; member of the Missouri State Medical Association; served during the World War; aged 59; on the staffs of the Providence Hospital and St. Mary's Hospital, where he died, February 2, of a skull fracture received in a fall.

James David Lowry, Fort Dodge, Iowa; State University of Iowa College of Medicine, Iowa City, 1901; member of the Iowa State Medical Society; past president of the state board of health; formerly county coroner and city health officer; aged 60; died, February 10, in the Mercy Hospital.

David Garrison Ghrist * Los Angeles; Harvard University Medical School, Boston, 1925; fellow of the American College of Physicians; on the staffs of the Los Angeles County Hospital, Hospital of the Good Samaritan and St. Vincent's Hospital; aged 38; died, February 3, of pneumonia.

Delmar Ivan Martin, Springfield, Ill.; Northwestern University Medical School, Chicago, 1929; member of the Illinois State Medical Society; president of the county tuberculosis board; served during the World War; aged 35; died, February 21, in St. John's Hospital, of pneumonia.

Carl Alfred Feige * Canova, S. D.; Hahnenmann Medical College and Hospital, Chicago, 1906; member and past president of the state board of health; served during the World War; on the staff of the Canova Hospital; aged 58; died, January 26, of carcinoma of the intestine.

Samuel Beaver Geise * Sunbury, Pa.; Medico-Chirurgical College of Philadelphia, 1903; served during the World War; on the staffs of the Evangelical Hospital, Lewistown, and the Mary M. Packer Hospital; aged 59; died, February 2, in Alcolu, S. C., of coronary occlusion.

Cecil Corwin Johnson * Le Claire, Iowa; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1901; formerly member of the city council of Le Claire; aged 59; died, February 18, in St. Luke's Hospital, Davenport.

Elbert Horton Downs, Montgomery, Ala.; Chattanooga (Tenn.) Medical College, 1900; member of the Medical Association of the State of Alabama; aged 66; died, February 13, in a local infirmary, of nephritis, cerebral hemorrhage and hypertension.

Fredrick R. Bueche * Steubenville, Ohio; Georgetown University School of Medicine, Washington, D. C., 1920; aged 41; on the staff of the Ohio Valley Hospital, where he died, February 6, of a skull fracture received in an automobile accident.

Henry M. Boies, Albany, Ill.; Jenner Medical College, Chicago, 1910; member of the Illinois State Medical Society; served during the World War; aged 57; died, February 24, in the Veterans Administration Facility, Hines, of pneumonia.

Joseph Cohen * Berwick, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1906; past president of the Columbia County Medical Society; on the staff of the Berwick Hospital; aged 54; died, February 10, of pneumonia.

Fred Louis Holcomb * Coldwater, Kan.; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1901; president of the Comanche County Medical Society; aged 59; died, January 31, following an automobile accident.

Luther Marshall Jayne * Niagara Falls, N. Y.; University of Buffalo School of Medicine, 1906; on the staffs of Mount St. Mary's Hospital and the Niagara Falls Memorial Hospital; aged 54; died, February 3, of coronary thrombosis.

Mary Agnes Laughlin, Hagerstown, Md.; Woman's Medical College of Pennsylvania, Philadelphia, 1898; member of the Medical and Chirurgical Faculty of Maryland; aged 68; died, February 2, of carcinoma of the breast.

Carl Henry Cunningham, Indianapolis; Indiana University School of Medicine, Indianapolis, 1928; member of the Indiana State Medical Association; aged 41; died, February 10, in St. Vincent's Hospital, of ulcerative colitis.

Ernest Watson Kelsey, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1894; member of the Medical Society of the State of Pennsylvania; aged 65; died, February 8, of cirrhosis of the liver.

Sarah Marcy Crawford, Newton, Mass.; Woman's Medical College of the New York Infirmary for Women and Children, 1877; member of the Massachusetts Medical Society; aged 92; died, February 15, of bronchopneumonia.

Benjamin Geret Gossow, St. Charles, Mo.; St. Louis University School of Medicine, 1922; member of the Missouri State Medical Association; on the staff of St. Joseph's Hospital; aged 40; died, February 8, of pneumonia.

Nathaniel Niles Morse, Goffstown, N. H.; Harvard University Medical School, Boston, 1904; member of the Associated Anesthetists of the United States and Canada; aged 60; died, February 24, of emphysema.

Leslie Frank Mulford, Philadelphia; Jefferson Medical College of Philadelphia, 1911; instructor in surgery at his alma mater; served during the World War; aged 53; died, March 6, in Miami, Fla., of heart disease.

Joseph Cooperstein, Flint, Mich.; College of Physicians and Surgeons of Chicago, School of Medicine of the University

of Illinois, 1909; aged 54; died, February 14, in the Hurley Hospital, of coronary thrombosis.

Charles J. Mooney, Washington, D. C.; College of Physicians and Surgeons, Baltimore, 1904; aged 62; died, February 3, in the Gallinger Municipal Hospital, of hypertensive heart disease and cirrhosis of the liver.

Joseph Franklin Moell, Lincoln, Neb.; Northwestern University Medical School, Chicago, 1907; member of the Nebraska State Medical Association; aged 58; died, January 21, of pneumonia complicated by meningitis.

Clarence Leslie Stammers, Los Angeles; California Eclectic Medical College, Los Angeles, 1914; aged 49; died, January 21, in the National Military Home, of bronchopneumonia and coronary thrombosis.

Willis Edwards Lowry Jr. Ⓢ Laredo, Texas; University of Texas School of Medicine, Galveston, 1924; served during the World War; on the staff of the Mercy Hospital; aged 40; died, February 6, of influenza.

John Ignatius McGuigan, Philadelphia; Jefferson Medical College of Philadelphia, 1887; on the staff of the Chestnut Hill Hospital; aged 70; died, February 19, in Bangor, Maine, of arteriosclerosis.

Harrell Myers Graham, Scranton, S. C.; Medical College of the State of South Carolina, Charleston, 1909; member of the South Carolina Medical Association; aged 51; was found dead, February 1.

William Margulies Ⓢ Brooklyn; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1890; on the staff of the Beth Moses Hospital; aged 68; died, February 8.

Arthur Edgar Kennedy, Washington, D. C.; University of West Tennessee College of Medicine and Surgery, Memphis, 1917; aged 42; died, February 6, in Lorton, Va., of influenza and pneumonia.

John William Boyd, Sarcoux, Mo.; Barnes Medical College, St. Louis, 1896; served during the World War; aged 65; died, February 3, in St. John's Hospital, Joplin, of septicemia and pneumonia.

Arthur T. Gregory, Mauston, Wis.; College of Physicians and Surgeons of Chicago, 1894; formerly secretary of the Juneau County Medical Society; aged 81; died, February 6, of pneumonia.

James David Howard Ⓢ Mount Lebanon, Pa.; Jefferson Medical College of Philadelphia, 1920; on the staff of St. Joseph's Hospital and Dispensary, Pittsburgh; aged 41; died, February 2.

Albert Columbus Lofton, Lucien, Miss.; Memphis (Tenn.) Hospital Medical College, 1906; served during the World War; aged 61; died, February 22, in a hospital at Brookhaven, of pneumonia.

Charles Franklin Doran Ⓢ Phoenixville, Pa.; Jefferson Medical College of Philadelphia, 1896; aged 67; on the staff of the Phoenixville Hospital, where he died, February 24, of pneumonia.

William Huey McCombs Ⓢ Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1895; on the staff of the South Side Hospital; aged 69; died, February 22, of coronary occlusion.

William Edward Gholson, La Center, Ky.; University of Louisville Medical Department, 1894; member of the Kentucky State Medical Association; aged 65; died, February 4, of pneumonia.

Thomas Linville Ⓢ Washington, D. C.; George Washington University School of Medicine, Washington, 1904; aged 62; died, February 1, of coronary occlusion and hypertension.

Edward Webster Bookhart, Wall Lake, Iowa; Lincoln (Neb.) Medical College of Cotner University, 1906; served during the World War; aged 56; died, February 9, of pyelitis.

Walter Asbury Newman, Manassas, Va.; Medical College of Virginia, Richmond, 1876; University of the City of New York Medical Department, 1878; aged 83; died, January 26.

Arthur Gilbert Bentley, Tipton, Tenn.; Memphis Hospital Medical College, 1910; aged 51; died, February 19, in the Baptist Memorial Hospital, Memphis, of pneumonia.

George Austin Carter, Hardwick, Vt.; Dartmouth Medical School, Hanover, N. H., 1890; on the staff of the Hardwick Hospital; aged 72; died, February 5, of influenza.

Wilhelmus Bogart Robinson, Ionia Island, N. Y.; New York Homeopathic Medical College and Hospital, 1888; aged 77; died, January 31, of carcinoma of the prostate.

Claiborne W. Evans, Modesto, Calif.; University of California Medical Department, San Francisco, 1881; aged 77; died, February 7, in San Francisco, of pneumonia.

Frank Borland Dake, State Sanatorium, Ark.; University of Tennessee Medical Department, Nashville, 1887; aged 72; died, February 15, of pulmonary tuberculosis.

Helen Robertson Howe-Gage, Suffield, Conn.; Woman's Medical College of Pennsylvania, Philadelphia, 1901; aged 69; died, January 6, of carcinoma of the sigmoid.

James Ambrose Malone Ⓢ Athens, Ohio; University of Cincinnati College of Medicine, 1924; aged 49; died, February 6, in the Mount Carmel Hospital, Columbus.

Elmer Ellsworth Cary, Ithaca, N. Y.; Bellevue Hospital Medical College, New York, 1887; aged 75; died, February 11, of chronic myocarditis and left hemiplegia.

William Carlile Caldwell, Wentzville, Mo. (licensed in Missouri in 1901); member of the Missouri State Medical Association; aged 65; died, February 15.

Charles William O'Donnell, Andover, N. Y.; University of the City of New York Medical Department, 1884; aged 76; died, January 28, of arteriosclerosis.

Charles B. Mulvey, Montpelier, Ind.; Medical College of Indiana, Indianapolis, 1894; formerly county health officer; aged 68; died, February 24, of influenza.

Patrick Henry Glancy, Parkersburg, W. Va.; Hospital College of Medicine, Louisville, Ky., 1892; aged 70; died, February 15, of cerebral hemorrhage.

Lazarus Sylvester Sobel, New York; University of Vermont College of Medicine, Burlington, 1894; aged 67; died, January 29, of coronary sclerosis.

Daniel Morris Harvey, Oakland, Calif.; Cooper Medical College, San Francisco, 1889; aged 81; died, January 31, of acute dilatation of the heart.

Edward S. Coats, Plains, Mont.; Kansas City (Mo.) Hahnemann Medical College, 1909; aged 66; died, January 15, of carcinoma of the bladder.

Arthur Eisbein, Buffalo; University of Buffalo School of Medicine, 1901; aged 62; died, February 13, of coronary occlusion and arteriosclerosis.

Mary Electa Clark, Chatham, N. Y.; New York Medical College and Hospital for Women, 1897; aged 91; died, January 8, of chronic nephritis.

George Wesley Beatty, Brooklyn; Long Island College Hospital, Brooklyn, 1898; served during the World War; aged 65; died, February 8.

Norman Buell Marshall, Chicago; Jefferson Medical College of Philadelphia, 1883; aged 76; died, February 26, of carcinoma of the ear.

Wadie Fadoul Courie, Detroit; Medical College of Virginia, Richmond, 1912; aged 51; died, February 14, in Kinston, N. C., of carcinoma.

Andrew Grassau, Caledonia, Ill.; Rush Medical College, Chicago, 1896; aged 68; died, February 10, in a hospital at Fort Myers, Fla.

De Witte Stone, Sayre, Okla.; Tulane University of Louisiana Medical Department, New Orleans, 1897; aged 63; died in January.

Monta B. Carr, Tazewell, Tenn.; Tennessee Medical College, Knoxville, 1902; county health officer; aged 66; died, February 10.

James T. Dicks, Nashville, Tenn.; Chicago Homeopathic Medical College, 1880; aged 84; died, February 8, of cerebral hemorrhage.

Hiram Davis Lofin, Henderson, Ala.; Medical College of Alabama, Mobile, 1904; aged 55; died, February 14, of coronary thrombosis.

William Fountain, New York; University College of Medicine, Richmond, 1898; aged 66; died, February 22, of coronary sclerosis.

Joseph Lynn Carnahan, Kansas City, Mo.; Kansas City Medical College, 1892; Civil War veteran; aged 92; died, February 6.

William Henry Woods, Mount Brydges, Ont., Canada; Trinity Medical College, Toronto, 1898; aged 65; died, January 27.

Merida F. Brown, West Hamlin, W. Va.; Kentucky School of Medicine, Louisville, 1905; aged 59; died in February.

James Lewis Pennington, Thedford, Neb.; Barnes Medical College, St. Louis, 1893; aged 68; died, January 27.

Bureau of Investigation

BENJAMIN GAYELORD HAUSER

Fruits, Vegetables—and Nuts

"Dr." Benjamin Gayelord Hauser, widely promoted for a while in various newspapers, is now billed in commercial food pamphlets of the Modern Health Products, Inc., of Milwaukee as a "World Famous Authority on Dietetics . . ." and "the famous Viennese scientist." He is not a doctor of medicine, not a Viennese and certainly not a scientist. Hauser endorses the concoctions of the Modern Health Products, and the Modern Health Products, of which Carl S. Hauser is vice president and treasurer, endorses Benjamin Gayelord Hauser.

In common with others of the mysterious men and women who appear out of the nowhere as "international scientists," "leading authorities on diet" and "world-famous lecturers on health," Hauser offers a series of free lectures on diet and health as a "come-on" for a special lecture course to be given at the conclusion of the free lectures. In addition, books, pamphlets and preparations of Modern Health Products, Inc., are recommended.

Unfortunately, the whys and wherefores of physiology, chemistry, anatomy and hygiene do not descend upon one as did the revelations of the prophets. Yet in some such supernatural manner must the "advertising scientists" have received their academic knowledge. For if these gentlemen and ladies of the lecture platform have left any record of their undergraduate training in accredited universities or colleges, it must have been as delicate as gossamer, and as intangible.

Hauser first came to the attention of the Bureau of Investigation in 1926, when a St. Louis newspaper announced that "Dr." B. Gayelord Hauser, "head of a New School of Health in Chicago," would give a series of free lectures in St. Louis. A Hauser class announcement of about the same period carried a quotation from George Starr White, M.D. "George Starr White—Quack" was the title of an article in THE JOURNAL for April 13, 1929, page 1292. In summary, the article stated: ". . . George Starr White is a quack who has commercialized the practice of medicine, who has no scientific standing, and whose opinions on matters dealing with modern medicine are wholly without value."

In 1926 the stationery used by a Helen Linch in writing for "Dr." Hauser to a Grand Rapids, Mich., inquirer, carried the heading "Bengaman Gaylord Hauser, M.D." A thorough search of the biographic files of the American Medical Association failed to reveal any one by the name of Bengaman Gayelord Hauser as a graduate of any medical college or licensed to practice medicine in any state in the Union. If Hauser was not trying to pass himself off as a Doctor of Medicine, the stationery used for him certainly left no doubt that Hauser was an M.D. It seems incredible that Hauser could have been represented as an M.D. without his knowledge, as Helen Linch was supplying "Special Information" on Hauser to all comers from the Morton Hotel at Grand Rapids in April 1926.

Hauser no longer uses the prefix "Dr." or the suffix "M.D."; he is content to be modestly known to his classes as "a nutritionist, a food scientist, a doctor of chemistry . . ." and admits: "I don't know beans about medicine. . . ."

If Hauser is a "doctor of chemistry" other than by self appointment, he failed in his class "announcements," distributed during his appearance at the Sherman Hotel, Chicago, in April 1936, to state from what academic institutions he acquired his knowledge of chemistry. Unless one is willing to accept the Hauser pronouncement that "Hauser's tremendous store-house of fundamental knowledge, coupled with the latest scientific facts he gathers each year in the great health centers of Europe . . ." is sufficient to confer on him the title "doctor of chemistry."

In his "lecture" at the Sherman Hotel on April 28, 1936, Hauser claimed to have attended the Chicago College of Naprapathy; his name did appear in the Chicago telephone book some years ago as a naprapath, although the records of the Department of Registration and Education of the State of

Illinois do not show that Benjamin G. Hauser was ever licensed under the Illinois medical practice act for treatment of human ailments by any system.

Hauser is a personable-looking, youngish man with a leading-man stage presence and a flair for the Jack Pearl-Baron Munchausen type of dialect ("smashed potatoes" for "mashed potatoes").

Benjamin Gayelord Hauser first entered the United States, according to a reliable authority, in 1911, from Tübingen, Germany, as Helmuth Hauser at the age of 16, and joined his brother, Otto Robert Hauser, then pastor of a church in Milwaukee. Thereafter little is known of Hauser's activities except what he tells from the lecture platform. Hauser states that he was dying of tuberculosis of the hip at the age of 16, which we have learned was his age when he entered the United States. He claims to have been given up by several famous Chicago physicians and returned abroad for treatment. In Switzerland, by accident, he claims to have met an old physician who prescribed lemon juice. Voila! Hauser was cured after one or two weeks of lemon juice. However, recovery from tuberculosis or some other serious illness by means of a special diet

Photograph of Benjamin Gayelord Hauser from one of his announcements, 1936.

is a claim made by practically all health faddists. In regard to his lemon juice treatment, Hauser warns his audience not to take thirty-six lemons a day, as he did!

Eugene Helmuth Hauser, now Benjamin Gayelord Hauser by court order, states that 50 per cent of the world's pains and aches could be cleared up by sodium, potassium and calcium. Hauser is extremely careful in his announcements to call attention to the fact that "personal consultations or interviews cannot be arranged, and it is clearly understood that his work in no way enters that field which pertains to the diagnosis and treatment of individual conditions." Nevertheless, chemist Hauser has no hesitancy in prescribing from the rostrum for various ailments submitted to him by card.

Hauser has a diet for practically every ailment to which mortal flesh is heir. There is the "Mending Diet" (with menus), the "Vitality Diet" (with menus), the "Transition Diet" (with menus), and the "Zigzag Diet." It is recommended that the "Zigzag Diet," together with "Syn," a preparation of the Modern Health Products, be taken by the overweight.

The three trump cards in Hauser's healing deck are sodium, potassium and calcium. One trained in the orderly method of the presentation of the sciences will suffer a series of academic shocks in attempting to follow Hauser in the ways of calcium, potassium and sodium. As a lecturer Hauser is as elusive as a rabbit; when you are prepared for a pronouncement of scientific fact the thought suddenly evaporates and Hauser is gracefully tacking his healing ship into a new angle.

As the Hauser meeting warms up, it takes on that electrifying something found only in religious revivals. Various members of the audience get up and testify to strange and unusual occurrences. An elderly woman testifies that her hair has turned from gray to brown as a result of the Hauser diet. Hundreds of hands were raised when Hauser asked how many had been free from colds since his last visit.

Hauser has ready answers for every question submitted to him by card, such as that every ear noise is due to a lack of red blood. To the question "How can I gain 25 pounds and spread it evenly over my body, not putting it on in spots?" Hauser answered, "When you balance your meals correctly, you don't put on weight in spots."

In reply to the question "What is good for pyorrhea?" Hauser stated: "Pyorrhea means anemic gums. Take lemon and hot water half and half."

To the question "What can I do to improve my hearing?" Hauser replies: "Hard of hearing people have mucus in the ear. Dissolve the mucus, flush, cleanse. If the ear drum is alive, you can improve your hearing."

Hauser also advised his audience: "Never take a trip across the ocean without 'Swiss-Kriss.'" Swiss-Kriss also is a concoction of the Modern Health Products, Inc., and was the subject of a Federal Trade Commission stipulation released on June 25, 1936. A few of the statements which the Modern Health Products, Inc., agreed to discontinue in their advertising were "that the product is a 'modern laxative' or a 'secret' of the Swiss people or that the formula was brought from Switzerland by health 'authorities'; that it will 'up-build' the system or that the product is a tonic or that it possesses tonic properties."

In September 1934 the Food and Drug Administration prosecuted the Modern Health Products, Inc., for selling two other products—"Santay-Swiss Anti-Diabetic Tea" and "Nutro-Links"—under fraudulent therapeutic claims. According to the government chemists, the first-named product consisted of plant drugs including peppermint leaves and stems, malva flowers, senna pods and dog grass, and Nutro-Links was composed of powdered plant material, common salt and Glauber's salt.

Another question asked at the Hauser lecture was: "What is vitality and why do so many people lack vitality?" Hauser answered: "If you are fat and eat a lot of fat, then your gallbladder is overworked and your gallbladder takes up a lot of energy."

Many more examples of the Hauser vagaries could be mentioned, but those cited should give sufficient information as to the type of advice Hauser dispenses.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

SYPHILITIC AORTITIS

To the Editor:—I am treating a patient for a syphilitic aortitis and have been treating him in about the same manner in which one would any chronic syphilis. This treatment has been over a period of a year and has consisted of alternating courses of bismuth and mercury compounds and neoarsphenamine, without intermissions. Does syphilitic aortitis call for special or different treatment? Please give me an early reply and omit name.

M.D., Texas.

ANSWER.—Cardiovascular syphilis requires specialization in its treatment. The two points to be emphasized in the treatment of cardiovascular syphilis are the effort to preserve the heart muscle and prevention of the progress of the syphilitic involvement. The Cooperative Clinic Group has shown that in patients with uncomplicated syphilitic aortitis the results of treatment are superior to those obtained in individuals with complicated syphilitic aortitis in that in the former group the life expectancy can be increased by treatment from thirty-four to eighty-five months after detection while in the complicated type the increase in life expectancy is from forty to fifty-five months after detection. The special treatment for syphilitic

aortitis includes first such measures as are indicated by the status of the heart. If signs of decompensation are present, rest in bed and the use of cardiac stimulants or sedatives is warranted. The antisyphilitic remedies in such patients should be limited to either mercury or bismuth compounds by intramuscular injection. These should be continued until compensation is reestablished, when small doses of arsphenamine may be given, preferably by the intramuscular route. Bismuth arsphenamine sulfonate or sulfarsphenamine is well suited for such cases. If neoarsphenamine is used intravenously, it is well to start with a dose of 0.05 Gm. and increase the dosage slowly. In the type of case mentioned in the inquiry, cardiac decompensation has apparently not been present, so that ambulatory treatment has been satisfactory thus far. As a general rule, however, it is recommended to start the treatment of all patients with cardiovascular syphilis with a bismuth or mercury preparation for at least a month before inaugurating one of the arsphenamines. Likewise, the physical activities of these patients should be restricted.

It is necessary to continue the treatment of patients with cardiovascular syphilis for a long time, and it is impossible to specify the number of injections of an arsphenamine or heavy metal preparation that should be administered in a given case because of the numerous factors that may influence such a decision. Chief among these, of course, is the progress, favorable or otherwise, which the cardiac lesion may show. In the case that responds favorably, small doses of arsphenamine in conjunction with either bismuth or mercury compounds should be given in courses twice a year for at least three years, following which courses of bismuth or mercury compounds alone should be given for three more years. Semiannual reexaminations are then warranted, as these patients are prone to have subsequent cardiac breakdowns. For the patients who progress unfavorably, the use of the antisyphilitic remedies is of secondary importance and when used should be given in small doses.

The ideal method of preventing cardiovascular syphilis is by the adequate and intensive treatment of early syphilis.

EXCESSIVE SWEATING AT NIGHT

To the Editor:—A man, aged 28, complains of severe night sweats and states that the odor of the perspiration is foul and rancid. He does not sweat during the day, although he does manual labor in an automobile plant. He is well developed and well nourished, is 68 inches (173 cm.) in height, and weighs 165 pounds (75 Kg.). Physical examination reveals no pathologic condition. His blood pressure is 118 systolic, 76 diastolic and the pulse rate is 72 beats per minute. His temperature is 98.6 F., without rise in the afternoon. There is no cough or expectoration. The Kline test is negative. Basal metabolism tests were made and the result was minus 4. Roentgenograms of the chest show the heart slightly enlarged and some evidence of an old healed pleurisy and slight chronic bronchitis. There is no evidence of tuberculosis. He has been given belladonna and potassium iodide solutions without any benefit. I would appreciate if you would aid me in the diagnosis and offer some advice as to further treatment.

M.D., Ohio.

ANSWER.—It seems that, of the ordinary causes of generalized hyperhidrosis, tuberculosis, rheumatism and hyperthyroidism have been ruled out. Anemia sometimes causes excessive sweating. A series of blood counts should be made with a differential count of the white cells and a sedimentation test. If anemia is present it should be treated with iron, arsenic or liver extract, as the type of anemia indicates. A rapid sedimentation test may point to some focal infection, which may be indicated also in the differential count.

In spite of a nonfebrile course and lack of an enlarged spleen, malaria may be suspected. The presence of secondary anemia with leukopenia may point to it, and a therapeutic test with quinine may be indicated, though of course not all that yields to quinine is malaria.

The negative Kline test and failure of improvement from potassium iodide do not rule out syphilis. Repeated Wassermann and precipitin tests should be made and the spinal fluid thoroughly examined.

The urine should be examined repeatedly, particularly for sugar, and the blood sugar should be estimated. Glycosuria is sometimes associated with hyperhidrosis. A thorough examination of the eyegrounds with a careful survey of the nervous system may reveal signs of dementia paralytica, myelitis, brain tumor or functional disorder as a cause of the excessive sweating. Finally the mental state of the patient must be studied. Neuroses due to fear may be responsible for hyperhidrosis.

A number of cases of self-limited generalized hyperhidrosis have been reported in which no etiologic factor could be found. The theory offered is that they were due to a temporary vasomotor disturbance in the corpus stratum or the hypothalamus consequent on some infection.

A study in the hospital is recommended. The amount of sweating and the odor can be noted. Neurotic patients often exaggerate body odors. The habits of the patient should be studied. Excessive drinking in the evening should be avoided. If no etiology can be discovered, symptomatic treatment must be used. Atropine and belladonna are seldom helpful because of the disagreeable by-effects. Stimulating baths, cold needle baths, alum, salt baths or alcohol baths are often helpful. Strychnine in stimulating dosage may be helpful.

DERMATITIS IN LEATHER WORKERS

To the Editor:—A man, about 23 years of age, single, complains of severe nervousness and a certain type of dermatitis, especially on the feet and hands, and the exposed part of the neck. The dermatitis of the hands and feet is similar to an eczema. He has had it for from six to nine months. He seems to be of a very neurotic type. He works in a glove factory and is working with leather ten hours a day. The question I wish to ask is: Is dermatitis caused by the handling of leather over a great period of time?

ROBERT WENDELL SHAW, M.D., Marinette, Wis.

ANSWER.—Yes, dermatitis is caused by the handling of leather. It is characteristic of sensitization that it may take place after long contact with the sensitizing material. However, manufacturing processes and materials are constantly being changed.

Dermatitis due to leather is not uncommon. In the preparation of leather, sumac, formaldehyde, chromic acid and tannin from myrobalan or quebracho are used in tanning, and ammonia or oxalic acid is used in finishing and polishing. Bismarck brown, chrysoidine and aurantia (emperor's yellow) are the dyes that give most trouble. Titanium chloride used as a mordant is very irritating.

Leather dressings may contain formaldehyde, mirbane oil, resins, white arsenic, asphalt, pearl ash, aniline, bismarck brown, oil of turpentine and possibly pine oils.

If it were not for the fact that most of these irritants are fixed, covered or removed in the process of manufacture, leather dermatitis would be much commoner than it is. The British Leather Manufacturers Research Association reported in 1932 that dermatitis due to leather was due probably to the presence of free chromic acid or to excessive amounts of water soluble dyes. This applies to shoes (London letter, *THE JOURNAL*, April 2, 1932, p. 1197). Glove leather is often tanned with formaldehyde. This may be the source of irritation in the case under discussion. Patch tests of the various substances that the patient handles should be made on healthy parts of the skin.

TACHYCARDIA WITH SYPHILIS

To the Editor:—In a man, aged 23, who was complaining of frequent headache, ostealgia, easy tiredness and tachycardia (with normal rhythm), it was discovered that the Kahn reaction was 4 plus. Physical and radiologic examinations were negative. An electrocardiogram revealed a hyperexcited myocardium without organic lesion. The basal metabolism and the blood cholesterol were within normal limits. He was then (June 17, 1936) given the following treatment: weekly injections for a period of nine weeks of 0.45 Gm. of nearsphenamine and of 0.1 Gm. of a bismuth compound (Iodobisman). From Aug. 1, 1936, to Sept. 25, 1936, I gave him 1 Gm. of Iodobisman. September 28 the Kahn reaction was negative. At present he is very much better except for the tachycardia, which disturbs him very much. Now and then he has attacks of paroxysmal tachycardia. What do you think of these attacks and their treatment? Are they related to smoking? I should like to know what your opinion is regarding the kind of syphilis of this patient. He never developed a sore on the penis or elsewhere. I am most interested in knowing whether it is possible to get syphilis without catching an initial sore (chancre). I. e., d'emblée. Will you please outline the treatment of this patient. If it is congenital syphilis is the treatment the same as for the acquired form? What is the treatment for paroxysmal tachycardia in this case? Please omit name and address. •

M.D., Brazil.

ANSWER.—Tachycardia due to syphilis is usually found in one of two situations. It may be present in the secondary stage when this stage is rather violent and associated with fever or it may be encountered in cardiovascular syphilis with mild or severe cardiac insufficiency. Neither of these conditions is present in this case, so it seems reasonable to doubt that the tachycardia and the syphilis are closely associated. This doubt is strengthened by the fact that the tachycardia was unimproved by the treatment, while most of the other complaints cleared up.

The causes of sinus tachycardia, and to a lesser extent of paroxysmal tachycardia, are multitudinous. Hyperthyroidism, the effort syndrome, and pathologic changes in the chest or abdomen include only a few of these causes. Both types of tachycardia are merely symptoms and it is unwise to treat any symptom if it is possible to ascertain the underlying cause. If the etiologic factor in the case of the paroxysmal tachycardia cannot be discovered or if it cannot be eradicated, the salts of quinine and quinidine have been found of value in preventing

the paroxysms. It is most difficult to slow a sinus tachycardia by means of medication. Recently derivatives of acetylcholine have been used in both types of tachycardia; but the use of these drugs is not without danger and should not be lightly undertaken. Tobacco may produce tachycardia in sensitive persons but certainly is not a common cause of this phenomenon.

It seems likely that the patient has an acquired syphilis. Congenital syphilis usually makes itself known before the age of 23 years and the absence of a known initial lesion does not carry much weight with syphilologists of large experience. It is assumed that in most of these cases the initial lesion has been extragenital and has gone unrecognized. Intra-urethral chancre is another source of confusion.

The use of the term "infection d'emblée" is ordinarily confined to those cases acquired by contamination with a syphilitic blood. This occasionally happens in blood transfusion, at the operating room table or at the necropsy table.

Whatever the source of the infection, there can be no criticism of the treatment carried out here. It should of course be followed up at suitable intervals and an examination of the spinal fluid should be considered before a complete arrest is assumed.

TOXICITY OF METHYL CELLOSOLVE

To the Editor:—Will you please state whether the fumes produced by mixture of methyl cellosolve with 80 per cent grain alcohol will produce any deleterious effects on the lungs of working people.

MURRAY BERGER, M.D., New York.

ANSWER.—Monomethyl ether of ethylene glycol is readily prepared by treating ethylene oxide with methyl alcohol in the presence of a suitable catalyst. The cellosolves, of which there are several, are useful solvents, as they at the same time partake of the properties of alcohols and of ethers. For this reason they readily dissolve a variety of organic substances. Because methyl cellosolve is derived from methyl alcohol and retains some alcoholic properties, it might be assumed that this substance is physiologically akin to its progenitor, methyl alcohol. Such is not the case and such alcoholic properties as are displayed by methyl cellosolve more closely resemble ethyl alcohol than the methyl variety. Reference may be found to the toxic properties of cellosolves in the *American Journal of Public Health* (19:525 [May] 1929). A more extensive discussion appears in *Public Health Reports* (45:1459 [June 27] 1930). However, this material is more closely related to ethyl cellosolve than to the methyl. This report is based on an experimental study from which it was determined that cellosolve vapors to the point of air saturation produce only a disagreeable odor, together with moderate eye and mucous membrane irritation. The statement is made that no indications were observed suggesting the possibility of chronic poisoning from ethyl cellosolve. While no large amount of data are in hand specifically referable to methyl cellosolve, there is no reason to believe that, in a mixture with 80 per cent ethyl alcohol, any marked deleterious effects on the lungs of workers are to be expected. Ethyl alcohol itself is not an entirely innocuous substance. As used in industry it is comparatively innocuous. It is believed that the presence of methyl cellosolve along with 80 per cent ethyl alcohol will give rise to no additional manifestations other than a moderate degree of local irritation.

NODOZ ANTISLEEP REMEDY

To the Editor:—Air line pilots have had recommended to their use a product known as "NoDoz" as a means of combating a tendency toward sleep. Will you please advise me of the formula of this product. Also, is any medicinal agent, other than citrated caffeine, recommended as a means of staying awake?

M.D., Florida.

ANSWER.—Some tests of a specimen of NoDoz made in 1934 indicated the presence of caffeine and an organic acid, probably citric. No other alkaloids were found. It was concluded that the tablets contained essentially caffeine citrate.

Misrepresentation of the therapeutic value of NoDoz Awakeners was charged by the Federal Trade Commission at Washington in a complaint issued against the NoDoz Laboratories, Inc., of Sacramento, Calif., on June 18, 1936. Among the representations cited by the commission were the respondent's alleged claims that NoDoz Awakeners are a pure vegetable concentrate and are used by more than a million automobile drivers, which claims, the complaint charged, were false or exaggerated.

Ephedrine, benzedrine and cocaine are other alkaloids that have a tendency to produce wakefulness; and their use, by reason of this tendency, should generally be avoided at bedtime.

POSSIBLE CANCER OF STOMACH

To the Editor:—A white woman, aged 49, housewife, nulliparous, seems to have a malignant growth of the stomach. On examination, the only positive pathologic conditions were a uterine mass the size of a grapefruit palpable superficially, with subserous fibroids vaginally and tenderness in the epigastrium. A hysterectomy was performed, and exploration of the abdomen revealed pathologic changes on the posterior wall near the cardia that appeared to be a malignant growth with possible glandular involvement; but the surgeon was unable to remove any tissue for biopsy because of the incision being too low down. Three weeks later the patient still complained of symptoms referable to the epigastrium, although occasionally to a lesser degree as compared to those before the operation. The surgeon wants to do a gastrectomy or whatever is feasible when the abdomen is exposed again. However, I fear a fatal outcome sooner than if a "hands off" policy is followed (perhaps with irradiation). The physical condition of the patient in general is good with exception of the blood pressure, 160 systolic, 100 diastolic. What is the wisest policy to follow, surgery or not? What treatment should be given then and what is the prognosis in either case? Kindly omit name if published.

M.D., New York.

ANSWER.—If examination by a competent roentgenologist confirms the diagnosis of malignancy to the exclusion of gastric syphilis, benign tumor and diaphragmatic hernia, one can hope to accomplish little by further surgical intervention. Inaccessibility of the lesion, and the prohibitive surgical mortality following subtotal or total gastrectomy, argue strongly against further operation. The prognosis under any circumstance is unfavorable, granted that the lesion is a malignant one. The treatment is largely symptomatic and palliative, although high voltage roentgen therapy might be carried out.

EPINEPHRINE IN PROGRESSIVE MYOPIA

To the Editor:—I wish to inquire into the use of epinephrine in the treatment of progressive myopia. I would be pleased to receive information on the length of treatment and on the dangers and contraindications of such treatment and finally on its apparent value. Please omit name.

M.D., Minnesota.

ANSWER.—The use of 1:1,000 epinephrine in the treatment of progressive myopia was introduced by Dr. Meyer Wiener of St. Louis and has been discussed in subsequent communications by various authors. In such cases epinephrine is used as drops into the conjunctival sac three times daily for long periods, at least three years or more, depending on the age of the patients. There appear to be no dangers or contraindications. The only untoward result appears when the solution becomes too old or becomes contaminated, especially by air fungi. The treatment appears to be of greatest value in young patients from between 8 and 12 years of age to early adolescence.

It is impossible to state absolutely whether or not the use of epinephrine arrests the progress of so-called progressive myopia, just as it is equally impossible to determine a priori whether any one case will progress or not. But in various series of patients of similar age and with like amounts of myopia there was definitely less progress in the myopia when epinephrine was used faithfully.

ENDOCRINE PRODUCTS FOR TESTICULAR DEVELOPMENT

To the Editor:—What is the status of endocrine products to develop small genitalia in a 9 year old boy? Both testes have descended. Please omit name.

M.D., California.

ANSWER.—There may be a question whether or to what extent artificial means should be directed toward enlarging the genitalia in a 9 year old boy whose testicles have descended. Aside from this question the general problem is still in the experimental stage, particularly as concerns the human being. The two means available for hormone stimulation of the accessory reproductive organs in experimental animals are (1) the injection of pure chemical extracts such as androsterone or testosterone (now prepared by synthetic means) and (2) the injection of gonadotropic agents to stimulate increased male hormone secretion by the intact testicle. Substances having these properties and prepared from human pregnancy urine or pituitary tissue are available for therapeutic use. It has been shown on experimental mammals that injections of androgen into the normal young growing animal has a decidedly retarding and injurious effect on the intact testicle. Continued injections of gonadotropic substances have been shown conclusively to stimulate testis hormone secretion in the experimental mammal and the reports of results from clinical applications, especially in cases of testicular undescended, have been favorable in some cases. Such treatments are yet too few, and the results

reported too uncritically weighed, to offer convincing indications of the efficacy of the measures adopted. A definitive answer to the question cannot be given at present.

NEEDLING OPERATION FOR CONGENITAL CATARACT

To the Editor:—I have two patients, aged 6 and 10 months, with congenital cataract. I would like your opinion as to the best time to do a needling operation. Since I have never operated on any patients this young I would like some one else's opinion as to the advisability of operating right away. Please omit name.

M.D., Virginia.

ANSWER.—The age at which congenital cataracts should be needed depends to a great extent on the character of the condition. If the lens opacities are accompanied by congenital miosis, it is not wise to attempt any operative procedure before the age of 6 years. But if the iris is normal and the pupil can be dilated widely, needling may be performed any time from the age of 18 months upward. There need be no fear that there will be failure of retinal development from lack of use by postponing the operation; on the contrary, there is no need of operating until the child is old enough to wear correcting glasses.

PERSISTENT PAIN AND EDEMA IN WRIST AFTER TRAUMA

To the Editor:—A woman, aged 25, injured her right wrist in the subway rush hour about two years ago by having it pinioned against a door post. Persistent pain followed this, accompanied by slight swelling of the fingers. The pain extends from the wrist to the fingers and is increased with edema when the fingers are used for such work as typing. For the past six months the patient had been symptom free until two days ago, when in getting off a chair she leaned heavily on her right hand and symptoms are again returning. The past history is negative; x-ray examinations on two occasions have been negative for fracture. What do you think is the diagnosis and treatment? Please omit name.

M.D., New York.

ANSWER.—Repeated x-ray examinations that are negative for fracture are not sufficient and the data are inadequate to make a diagnosis or advise treatment.

What about the calcium content of the bones? Is there demineralization or osteoporosis? This case may be in the classification of osteo-articular-vascular-neurogenic lesions. The present attack may be a mild recurrence. There may be a malacia of the carpal bones. Foci of infection should be investigated. Some of these patients do well on occupational therapy and some require sympathetic denervation. Excellent literature on this subject will be found in articles by Clarence H. Heyman of Cleveland, Gurd of Montreal, Leriche and Fontaine of France and R. Watson Jones of Liverpool.

PEPSIN SECRETION OF LOWER ANIMALS

To the Editor:—I should be greatly obliged if you could inform me whether the stomachs of the calf and cow are known to secrete any pepsin. If they do contain pepsin, could you let me know whether any of the larger animals (domestic) secrete a pepsin-free gastric juice? I should also be grateful for any references on the gastric physiology of these animals. Please omit name.

M.D., Canada.

ANSWER.—Pepsin seems to be normally present in the stomach secretion of all species of vertebrates, certainly from the amphibians up. There appears to be some uncertainty as to the character of the gastric enzyme in fishes. In the ruminating mammals, pepsin is secreted in the last division or true stomach. Of course not all vertebrate species have as yet been examined for gastric pepsin. As to gastric pepsin in calves, the pepsin and the hydrochloric acid of the gastric juice appear at or shortly before birth, in those species so far studied.

HYPERPYREXIA FOR TREATMENT OF GONORRHEA

To the Editor:—We note in Queries and Minor Notes of March 27, 1937, the report of a case of chronic periurethral abscess with persistent presence of gonococci. In the reply to the query concerning treatment, it is stated that artificial fever therapy is rather heroic treatment for this condition, and further local treatment is recommended. A persistent gonococcal infection of fifteen months' duration is by no means a trifling affair, especially as far as the patient and his possible contacts are concerned. This patient has been offered rational local treatment, but the infection still persists. Hyperpyrexia in experienced hands conducted under control of a physician doing fever therapy has proved its merits in eradication of gonococcal infections. It is now time to correct the general impression that hyperpyrexia is heroic treatment. As this form of therapy is today conducted, it is neither dangerous nor debilitating. Since all workers in artificial fever therapy report from 88 to 92 per cent cures in all types of gonorrheal infection, this therapeutic measure should be definitely encouraged in persistent gonorrheal infections.

SYMPOSIUM ON THE SELECTION OF STUDENTS

Primary Mental Abilities

L. L. THURSTONE, PH.D., Chicago: While the complex known as intelligence is very useful in differentiating those who are generally bright and those who are less endowed, it is of great importance to isolate those elements of intelligence which are in some fundamental sense primary. Common experience supports the view that such differentiable types exist and that mental endowment cannot be adequately described in terms of a single index. This problem has been the subject of speculation for centuries, and every writer has been at liberty to set up his own classification and to argue for its acceptance. A scientific treatment, on the other hand, demands that the elements of intelligence be demonstrated by objective experimental methods.

Scientific work that has been in progress for the past four years has revealed seven primary mental abilities. While future investigation will refine our present ideas about each of the primary abilities, it is possible already to describe the general characteristics of seven of them. The present list of seven primary factors was isolated by the application of factor analysis to the records of 240 college students who volunteered fifteen hours of work in taking fifty-six psychological tests. One of the most conspicuous primary abilities that appeared in these experiments was number facility. This primary factor is entirely restricted to numerical thinking and it is present in the highest amount in simple numerical speed tests. It is less conspicuous in those numerical tests which involve reasoning or formulation of a problem in quantitative terms. Another primary ability conspicuous in these experiments is word fluency. A test of anagrams has a large component of this ability. In one of the best tests for this factor the student is asked to identify words that are presented with their letters in disarranged order. Another similar task is to write as many words as possible that have the same general meaning as some given word. The visual material in these experiments was adequate for the isolation of a primary ability of visualizing. As far as can be determined at present, this factor includes the visualizing of solid objects as well as flat space. Again there seems to be experimental justification for describing some persons as visually minded. A distinct memory factor was revealed in the analysis. The memory tests were varied in content so as to involve memory for names, words and numbers, and tests were included in order to ascertain whether recognition memory among distractors would reveal several memory factors. The conclusion seems warranted that a person can be described as having a good memory in general without specification as to what he can remember well. One of the seven primary abilities has been called perceptual speed. It is prominent in those tests in which the subject is asked to identify something quickly when it is mixed with other perceptual material. In one of these tests the subject is shown a figure with some detail of design. He is also shown five others that differ but slightly and he is asked to pick out the design that is an exact duplicate of the given design. This is the ability that enables some people to scan a page of names

or numbers to find a particular item quickly while others must examine each item separately. A most interesting primary ability that has appeared in these experiments is one that has been named induction. It is involved in several tasks which have in common the characteristic that the subject must discover some principle or rule that governs the material. Another primary ability has been named verbal reasoning. It is exemplified by tests of verbal analogies and tests in which the subject is asked to match proverbs which have the same moral or quotations which have the same meaning, and to make numerical estimates which require deductive reasoning.

The practical result of these tests is that individuals can be appraised as regards each of the primary mental abilities. Instead of describing a child or an adult by means of a single index of intelligence, the description will be in terms of at least seven indexes which can be graphically represented on a diagram in a sort of profile. The ups and downs on an individual's mental profile show the primary abilities in which he is gifted and the abilities in which he is not gifted. Such a description is in line with common observation about people according to which they differ not only as to a single average mental level but also in the diversity of individual talent.

In vocational and educational guidance, the mental profiles will play an important rôle. Children may be divided into separate groups in the schools in accordance with their mental profiles and taught to read, for example, by methods that are appropriate to their respective imagery types. An engineering student who is relatively deficient in visualizing will be warned beforehand of his difficulty with descriptive geometry. The medical student who is relatively low in memory will know beforehand that he will have to give special effort in learning anatomy. Unsuspected talent might be discovered by rating people on each primary element of intelligence.

One of the most fundamental educational problems is to determine to what extent these primary abilities are native and to what extent they can be trained. If it should be found that some abilities can be trained, school curriculums might be fundamentally altered. It will be of great social interest to ascertain which abilities are determined by inheritance. Since the primary mental abilities have so recently been isolated, there must be several years of intensive research before the appropriate tests can be made generally available for all ages. Further experimental studies must also be made in refining our conception of the primary abilities.

Measurement of Personality

EDWARD K. STRONG JR., PH.D., Stanford University, Calif.: There are two major problems in the selection of students for a medical school. First there is the problem of selecting applicants who will do satisfactory scholastic work in school. Second there is the problem of selecting applicants who after graduation will be successful practitioners, enjoy their work and be a source of pride to the profession. This paper is primarily concerned with the problem of selecting students who will make good in actual practice after graduation. Here a wide variety of factors needs to be taken into account. Consideration should be given to such characteristics as honesty, willingness to work, faithfulness in performance of duty, lack of tendency to get drunk, and the like. Without such qualities a man cannot be trusted and hence will not be employed even though he did fine scholastic work in medical school. Consideration ought also to be given to those aspects of personality which will win clients and the cooperation of colleagues.

One approach to this problem of selecting men for a profession who will enjoy their work throughout life is through the use of the vocational interest test. This is a test of what one likes and dislikes. It is not a measure of intelligence. Certain general conclusions can be stated following thirteen years of research and the analysis of thousands of records of men in more than forty different occupations. First, adult men engaged in a particular occupation have a characteristic pattern of likes and dislikes which differentiate them from men engaged in other occupations. Second, occupations can be grouped according to the similarity of the interests of the men engaged in those occupations. Third, these occupational interests are not the result of experience from working in the occupation, for college men and high school boys possess such

interests before they have had any actual experience in the occupation or even in many cases before they have studied the subject.

Each of our 285 college seniors has been assigned to the single occupation in which he rates highest. On this basis it is found that 4.6 per cent of these college seniors have more distinctly the interests of physicians and surgeons than any other among twenty-seven occupations. These percentages must be viewed as tentative, but they suggest that there are enough young men definitely possessing the interests of medical men to fill the medical schools.

The interest test purports to differentiate those who have the interests of successfully employed men in a given occupation from those who do not have such interests. And the claim is made that the former are more likely to enter the occupation and continue in it than the latter. If a professional school is desirous of securing students who will continue throughout the entire course, it should see to it that students have the ability to do the work and the interest to continue in such studies. Too many educational institutions are interested primarily in filling their classes with students and are little concerned with whether those students belong there or somewhere else so long as the students obtain sufficiently satisfactory grades and continue on to graduation. Should not every educational institution be primarily concerned in directing students into the pathways which they are best fitted to follow? From the data in my possession it is clear that if this should be done there would be a considerable interchange of students, with the result that many more students would be trained for the occupation they are best fitted to follow and educational institutions would have fewer misfits in their specialized training courses.

We are in no position to carry out such a program in a thoroughgoing, efficient way because we lack the measuring devices which are necessary for determining individual fitness. A beginning can be made, however, employing the devices which we now have at our disposal. The vocational interest test is such a device. If it should be given, for example, to all college students in their sophomore year, some now heading for medicine would be encouraged to try something else and some not now considering medicine would enter the profession. The interest test can possibly be used as a selective device in considering applicants for admission to medical school. It should be tried out in this connection on an experimental basis. The danger to guard against is the fact that students can fudge the results if they wish to do so, unless possibly they are required to take it in a designated minimum time. But the real place to use the interest test is when students are honestly trying to make up their minds what they should do. Under these conditions they give honest responses to the test items.

The Why, What and How of the Medical Scholastic Aptitude Test

DR. TORALD SOLLMANN, Cleveland: The tests devised by Dr. F. A. Moss, which have been given nationally for several years by a committee under the auspices of the Association of American Medical Colleges, aim to test a student's ability to master the study of medicine, to appraise his chances of getting through the medical school, and to forecast whether he is likely to rank as an outstanding, a good, a fair or a poor student in medicine. The test does not pretend more than this. Granting that it is desirable to know the medical scholastic aptitude of the applicants in order to select them, is it necessary to institute a special test for it? The applicant has been studying at a college; could not the college tell us all about his scholastic aptitudes or ineptitudes? Do not his grades tell the story. Sometimes they tell it very well indeed, better than any test; sometimes they tell it not very well and sometimes not at all, or they may even distort it out of all recognition.

It may be just, but it may also be unwise, to close the door automatically on account of college grades which may be the result of faults of judgment of a youth who has not yet found himself; it may be an undeserved calamity to him, and perhaps to humanity, for some good material will certainly be discarded. Linnaeus, I believe, was expelled from secondary school for stupidity, though with the saving grace of a "hope that, like some trees in a nursery, he might thrive better

after transplanting." The scholastic aptitude test gives the student a final chance to show whether his low grades were caused by something else than native ineptitude. At the same time, it helps to nail lame excuses, so often heard and so difficult to answer, that the grades would have been quite different if this, that or the other. If low grades and low aptitude test ranking coincide, there remains no room for alibis. It is in the middle group, however, in which an additional test is especially necessary to separate the collegiate sheep and goats. The case is somewhat parallel to diagnosis in medical practice. The extremes of illness and health can generally be diagnosed satisfactorily by the direct physical signs, but not always, and laboratory tests and x-ray plates will pick up something important here and there that would have been missed without them; and whenever the older methods leave room for doubt, and especially for prognosing and comparing intermediate cases, the physician would use every means available to him and not be content with a method that amounted to a 50 per cent probability, if this could be checked by another method of examination. The best diagnosis is not furnished by any single method but by the checks and counter-checks of several independent methods.

What is the Moss test? How does it manage in two hours to give a generally reliable estimate of a student's ability for the study of medicine, more reliable on the whole than his two, three or four years of college grades? The test approaches its problem from several rather distinctive angles. First it tries to depart from the beaten paths of course examinations, so that it cannot be prepared for, at least directly. It aims to sound what is left of the previous knowledge and experience of the student after most of the forgettable things have been forgotten. Through this it aims to reach the student's real interests and his power of selection for these. Then it aims to test the ability of the student to apply his knowledge remote from its usual context and thus again to distinguish what has become a part of the student from that which became part of an animated phonograph. At the same time, this tests the ability of the student to face new situations on his own. Then again it sets certain rather difficult study tasks, not requiring any previous knowledge of the subject but testing the ability to handle the sort of tasks with which the medical student is faced; and, finally, the whole test is a test of the ability to work under some pressure, which is so necessary in the study of medicine. These are broadly the distinctive aims of the test, and their application is checked every year by Dr. Moss and his staff by comparing the correlation of the several parts of the test with the grades of the students in the medical school, and the different parts of the test are then given more or less weight, or dropped, according to how they pass this test of achievement. New approaches are introduced tentatively and tested, retained or abandoned in the same manner. In this way it is hoped to make the tests ever better and to keep them from becoming stereotyped.

It should not be expected that the testing of men by men will ever be perfect. The genius of men differs in all things, and aptitude tests are no exception. They are meat to some and poison to others. Some men have a special knack for working out puzzles and like them, and others abhor them. The good correlation of the aptitude test with premedical and with medical grades shows that personal reactions are not generally serious; but when they are material in an individual case, this is of course shown by a sharp divergence of college grades and aptitude test, so that the admission officer may look into the matter and make his decision with this in mind. Previous practice in taking the aptitude test generally brings some improvement, but the official rating of the applicant shows whether he has taken the test before, and the grades can then be compared and the "practice improvement" discounted. Efficient proctoring is the only protection. Special training for the aptitude test is nearly akin to cheating, since it aims to secure an unfair advantage over other applicants.

No one, I imagine, has ever seriously proposed to use the aptitude test as the sole criterion for the selection of applicants. It is merely one factor in the diagnosis and prognosis. Even for scholastic aptitude it should be appraised with an eye to the college grades; and, when these together indicate the ability of the applicant to master the study of medicine.

other factors which play an important part in the practice of medicine must be considered, especially character and the features generally grouped as "personality and background." Until a method is devised of expressing the quality of a competent, conscientious practitioner in mathematical terms, conclusions must be based on sense and logical deductions.

DISCUSSION ON THE SELECTION OF STUDENTS

DR. IRVIN D. METZGER, Pittsburgh: We have had this morning a discussion from the point of view of the psychologist and the educator, who start and predict the likely person, the possibilities of the young man. The secondary schools are attempting to do that all over the country at present. It is interesting to those who catch these people after they have been trained, apparently, for the work which they are to do. Somehow, it is felt that many of them have not been touched quite as they should have been to make the best type of practitioners. There has been a misfit somewhere. I suspect it is in the personality rather than in the training. Personality is a very difficult thing to determine. So it is in the matter of education. Certain personal factors that are sure to crop out cannot be evaluated. I think the matter of interest has a great value, however, in any line of study. In the older cultures, as they exist in Europe, the young man or young woman is apt to follow the type of life which the parent has followed. That is not true in America; in fact, it seems in America to be the opposite. The technic of finding out whether a man will make a good physician, even when he comes before the state board, is inadequate.

DR. T. E. BROADIE, St. Paul: Three general characteristics are extremely important: first, intelligence. There are many ways in which one can learn about a student's intelligence. The second is character. Every one knows pretty well what is meant by fine character. The third is personality. This is the most indefinite and difficult characteristic to evaluate. A personal interview with the committee on admissions, preferably at the school, or meetings arranged elsewhere if necessary, is extremely important. If these meetings are informal, it is extraordinary what unusual matters may be found out in the course of half an hour's interview.

DR. FRANK M. FULLER, Keokuk, Iowa: Men and women of the highest grade of intelligence, the greatest aptitude for accomplishment, may go through the medical course, but if those men and women go out into the community without the qualities of honesty, integrity and moral stamina they will never make good physicians. I believe that in all our tests, as has just been said, a personal interview gives a better idea of the quality of the man. The man who will go out into the community and act fairly and act justly and act rightly will be the man who should be selected as the possible student and practitioner of medicine.

DR. TORALD SOLLMANN, Cleveland: The matter of character, of course, is really important. It did not happen to be a part of this morning's program. I am sure that the personal interview is the most efficient method of appraising. I think our experience has been that on the whole we tend to learn more by the appraisals of the man under whom the student has been in college than we can learn from the interview, although it is not, of course, without value.

SYMPOSIUM ON TECHNIC OF EXAMINATIONS

Philosophical Comments on Examinations

DR. HOWARD T. KARSNER, Cleveland: This article was published in full in *THE JOURNAL*, March 27, page 1022.

Fundamental Purposes, Methodology, and Technics of Examining in Relation to Medical Education and Licensure

BEN D. WOOD, PH.D., New York: The fundamental purpose of medical examinations is to secure information about individuals which will enable us to judge their suitability for admission to and promotion in medical schools, and for admission to medical practice. Medical education is a privilege which should be accorded only to those who have the ability

and character to be worthy members of the profession and faithful servants of both the sick and the well. The funds for medical education are so inadequate, and are invested with such a crucial public interest, that any waste of them on incompetent or unsuitable students is a social loss which multiplies itself as time goes on. If such wastes are knowingly allowed for any reason, or even if they result only from negligence, a social crime has been committed which is incompatible not only with the Hippocratic oath but also with the ordinary rules of decent citizenship. If such negligence proceeds to the extent of licensing candidates who are incompetent because of either intellectual or moral deficiencies, a crime is committed which, at least potentially, is nothing short of heinous and revolting. On the other hand, it has been asserted by some authorities that good medical men are so rare that the exclusion of even one good man by unduly severe standards would entail a potentially great loss. But since one incompetent or unfaithful doctor can do more harm than ten can prevent or repair, let us err, if at all, on the side of humanity and the integrity of the profession, rather than endanger both for the sake of a few doubtful candidates.

The devices and methods now commonly used for selection are inadequate, and better ones are available if we would make the adjustments required by them. In common with most other professional colleges and licensing boards, those concerned with medicine have taken the matter of personnel selection rather lightly, not to say nonchalantly. They have more or less passively accepted traditional devices and methods. Technical advances in the construction and interpretation and use of examinations have been largely ignored and in some cases denounced. The obvious inadequacies of traditional devices have led to some discussion but not to any systematic or organized research in the field of medical aptitudes, achievements, interests or personal characteristics and methods of identifying and measuring or describing them. This is surprising, because medical diagnosis and medical case records have for many years served as an inspiration for workers in the field of educational and vocational guidance. We need educational, intelligence and personal and moral diagnosis comparable with modern medical diagnosis if we are to improve the selection of candidates for medical education and practice. This is a high ideal which will not soon be reached, but we can move toward it if we can catch the spirit and adopt the methodology that have led to the remarkable triumphs of modern medical diagnosis. The devices and examinations now used by colleges and boards are not nearly as accurate as the clinical thermometer and stethoscope, and even if they were as accurate they would no more be adequate to meet the admission and licensure problem than the thermometer and stethoscope alone would be adequate to meet the diagnostic problems of the general hospital of a large city.

The examinations now generally used in medical colleges and by licensing boards suffer from several technical imperfections: 1. Subjectivity. The examinations are almost exclusively of the essay-writing type. As usually employed, the written examination is highly subjective, from the selection and wording of the questions through the process of evaluating the answers and interpreting the resulting grades. 2. Inadequate sampling of materials and performances. Since the student must write out his answers in long hand and since only a few pages can be written in examination periods of normal length, the sampling of the materials on which the examination is based is necessarily narrowly limited. Since the number of questions is limited and each represents a large percentage of the total score, chance elements play a large and often decisive part in determining the final score. Since writing is in some degree a special art which involves abilities and habits often irrelevant to the purpose of the examination, and since students, like their examiners, vary from day to day in their effective writing, and since only a few brief samplings of the students' writing are secured, several additional chance and irrelevant elements are often present in vitiating degree. These weaknesses, plus the subjectivity of the rating, are the main sources of the low reliability and low validity of the traditional types of examinations as traditionally administered. 3. Statistical unreliability. Most if not all studies of the essay-type examination agree in indicating a relatively low statistical reliability.

Objective types of examinations which are carefully made usually show much higher reliability, unit for unit of examination time. 4. Low validity. The most serious consequence of all these technical defects is the generally low validity of the essay or written examination as normally used. Essay examinations constructed by the same examiners and designed to measure the same functions in the same pupils do not usually agree more than 50 per cent better than chance, even when allowance is made for their statistical unreliability. Even carefully made college entrance examinations in English, in which the written examination would appear a priori to be at its best, rarely predict a whole year of college grades in English more than 10 or 20 per cent better than chance. 5. Lack of comparability. Another serious defect of the traditional examination, as generally used, is the lack of comparability in the resulting grades or percentage scores. The questions, chosen subjectively, vary enormously in their difficulty, and the standards by which the answers are evaluated vary from reader to reader, and from day to day in the same reader.

I make these strictures on the traditional examination only as it is traditionally and generally used. Most of these defects can be greatly reduced or eliminated by careful procedures such as those used in recent years by the College Entrance Examination Board and by the Board of Examinations of the University of Chicago. Thus what I have chiefly denounced here is not the old-type or essay examination per se but rather the traditional misuse and misapplication of the written examination and the failure to use supplementary types of tests both for their intrinsic advantages and for their value in minimizing the defects of the written type of examination.

As in other educational institutions, the first duty of the medical college is not to teach but to learn students—to learn whether they belong in medical college and, if so, what specialties they might best pursue, if any. That this first duty has not been satisfactorily discharged by higher institutions generally is indicated by the high and increasing academic mortality rates in our colleges of liberal arts, of engineering and of law. The traditional examinations have not merited the confidence which we have reposed in them. The objective forms of tests will by no means furnish panaceas for all the maladjustments in our educational system, but that they are capable of giving us more exact and more meaningful information about our students than the traditional examinations alone has been demonstrated beyond reasonable doubt.

The Essay Examination "On the Spot"

DR. ROBERT P. DOBBIE, Buffalo: A recent survey made by questionnaire, to which seventy out of seventy-five universities responded, indicates that sixty-four of these seventy schools, or 92 per cent, use written final examinations either alone or combined with oral examinations in the senior year of the medical school. It was also learned, from the information furnished by sixty-one of the responding schools, that fifty-eight, or 95 per cent, use examinations made up for the most part of essay or "discuss" type questions. One concludes, therefore, that the usual written final examination given in most medical schools as well as by the national and state boards of examiners, is generally made up of varying numbers of essay or "discuss" type questions. It is my observation that the essay or "discuss" type questions are, as a rule, poorly designed; furthermore, frequently the same questions are repeated with slight, if any modifications, year after year. They are extremely narrow in their scope and many of them are poorly worded, requiring indefinite, lengthy answers which are extremely difficult, if not impossible, to grade or rate. The essay question gives the student the opportunity to write for an indefinite length of time on a subject he may know little or nothing about. Any one who has had the opportunity to examine these examination papers thoroughly appreciates the difficulties encountered in going through page after page of illegible writing, hoping to find, and recognize, points which the question was supposed to bring out. One often finds, if anything at all, a maze of impressions scattered amidst much irrelevant discussion. Some facts, though accurate, are later voided as the student rambles on, trying to get in every possible thought which he considers even remotely connected with the subject.

The experienced examiner has also realized how the severity in grading answers to the essay question varies, not only with different examiners, but with the same examiner, according to circumstances. That these difficulties and many others are actual, not merely hypothetical, has been proved many times in the college of arts and sciences and now for the first time, or again, in a college of medicine.

A study was carried out last year in the Medical School of the University of Buffalo, where, for the past four years, I have been acting as chairman of the examination committee. Sincere efforts to grade reliably 128 essay question manuscripts (submitted by sixty-four students) by eight competent examiners proved futile though a greater than usual attempt at unified estimation was made. The grades assigned by the individual examiners were studied and compared in two departmental groups, each comprising four examiners, as well as in one group of eight examiners.

Grading of the same manuscript by four different examiners resulted in a tremendous variation of grades. The point spread between highest and lowest grade assigned each manuscript was more than ten points in 60 per cent of instances and more than fifteen points in from 35 to 50 per cent of instances, depending on which group of examiners is considered. The grade variation of the two groups of examiners (four each) was manifested in no lesser degree, and correlation between the two groups was conspicuous by its absence. No relationship between the two questions is suggested, though they are both important medical subjects.

Examiners grading the same batch of manuscripts after several months' lapse of time showed tremendous variation in their own grades, which completely changed the status of a sizable proportion of the class.

Reliability in grading was in no way improved by grading in groups instead of by percentage grade.

Forty-four, or 60 per cent, of the class of sixty-four students were questioned or failed by one or more of the eight examiners, but, on analysis, practically all were unjustified if the consensus (of all participating examiners) was used as the determining factor.

In this demonstration, at least, it is shown quite conclusively that the resultant grades on manuscripts written as answers to typical essay or "discuss" type medical questions are thoroughly unreliable and are of little or no use in determining the general ability of a student on either an individual or a competitive basis.

Because of the marked variation in assigned grades shown among the examiners of the same department as well as between the two departmental groups of examiners, it is concluded that the more examiners participating, the greater the confusion and the more impossible it becomes to arrive at a valid estimate of the knowledge displayed in a given manuscript.

It is the purpose of this demonstration to discredit an examination system which is in more or less universal use throughout the medical schools. Such a system, because of its significance and power, should certainly be reliable and as nearly above criticism and the influence of chance as possible. I believe that the exact opposite has been shown to be true. I believe that the usual written essay question in use today is most unreliable and should be condemned. If it has any use at all, marked modification or change in design seems imperative. If reliability in grading cannot be assured, it should be abolished. At the University of Buffalo for the last four years we have used a better type of examination, which has received the enthusiastic endorsement of both students and faculty. It is, in our opinion, a superior examination in that it is more comprehensive as well as inclusive. Consisting entirely of short answer, "objective test" questions, it requires in the answering a maximum amount of thinking with a minimum amount of writing. The ability to judge knowledge and judgment, as well as the power of correlation and interpretation, is not sacrificed. It must be, and is, designed with the greatest of care and takes months in preparation. This is compensated for, however, in the fact that it can be graded quickly, easily and reliably.

(To be continued)

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

ALABAMA: Montgomery, June 22-24. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

ARKANSAS: *Basic Science*. Little Rock, May 3. Sec., Mr. Louis E. Gebauer, 701 Main St., Little Rock. *Medical (Regular)*. Little Rock, June 17-18. Sec., Dr. A. S. Buchanan, Prescott. *Medical (Eclectic)*. Little Rock, May 11. Sec., Dr. Clarence H. Young, 1415 Main St., Little Rock.

CALIFORNIA: *Reciprocity*. San Francisco, May 9. *Examinations*. San Francisco, June 28-July 1, and Los Angeles, July 19-22. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

CONNECTICUT: *Basic Science*. New Haven, June 12. *Prerequisite to license examination*. Address State Board of Healing Arts, 1895 Yale Station, New Haven. *Medical (Homeopathic)*. Derby, July 12. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven. *Medical (Regular)*. Hartford, July 13-14. *Endorsement*. Hartford, July 27-28. Sec., Dr. Thomas P. Murodock, 147 W. Main St., Meriden.

DELAWARE: Dover, July 13-15. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, Dover.

DISTRICT OF COLUMBIA: *Basic Science*. Washington, June 28-29 (probable dates). *Medical*. Washington, July 12-13. Sec., Commission on Licensure, Dr. George C. Ruhland, 203 District Bldg., Washington.

FLORIDA: Jacksonville, June 14-15. Sec., Dr. William M. Rowlett, Box 786, Tampa.

HAWAII: Honolulu, July 12-15. Sec., Dr. James A. Morgan, 48 Alexander Young Bldg., Honolulu.

ILLINOIS: Chicago, June 22-25 and Oct. 19-21. Superintendent of Registration, Department of Registration and Education, Mr. Homer J. Byrd, Springfield.

INDIANA: Indianapolis, June 22-24. Sec., Board of Medical Registration and Examination, Dr. William R. Davidson, 301 State House, Indianapolis.

IOWA: Iowa City, June 8-10. Dir., Division of Licensure and Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines.

KANSAS: Topeka, June 15-16. Sec., Board of Medical Registration and Examination, Dr. C. H. Ewing, 609 Broadway, Larned.

KENTUCKY: Louisville, June 9-11. Sec., State Board of Health, Dr. A. T. McCormack, 532 W. Main St., Louisville.

MARYLAND: *Medical (Regular)*. Baltimore, June 15-18. Sec., Dr. John T. O'Mara, 1215 Cathedral St., Baltimore. *Medical (Homeopathic)*. Baltimore, June 8-9. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore.

MICHIGAN: Ann Arbor and Detroit, June 9-11. Sec., Board of Registration in Medicine, Dr. J. Earl McIntyre, 202-204 Hollister Bldg., Lansing.

MINNESOTA: Minneapolis, April 20-22. Sec., Dr. Julian F. DuBois, 350 St. Peter St., St. Paul.

MISSISSIPPI: Jackson, June. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

MISSOURI: St. Louis, June 14-16. State Health Commissioner, Dr. H. F. Parker, State Capitol Bldg., Jefferson City.

NEBRASKA: *Basic Science*. Omaha, May 4-5. *Medical*. Omaha, June 8-9. Dir., Bureau of Examining Boards, Mrs. Clark Perkins, State House, Lincoln.

NEVADA: Carson City, May 3-4. Sec., Dr. John E. Worden, Box 630, Carson City.

NEW JERSEY: Trenton, June 15-16. Sec., Dr. James J. McGuire, 28 W. State St., Trenton.

NEW YORK: Albany, Buffalo, New York and Syracuse, June 28-July 1. Chief, Professional Examinations Bureau, Mr. Herbert J. Hamilton, 315 Education Bldg., Albany.

NORTH CAROLINA: Raleigh, June 21. Sec., Dr. Ben J. Lawrence, 503 Professional Bldg., Raleigh.

NORTH DAKOTA: Grand Forks, July 6-9. Sec., Dr. G. M. Williamson, 4½ S. 3rd St., Grand Forks.

OKLAHOMA: Oklahoma City, June 9-10. Sec., Dr. James D. Osborn Jr., Frederick.

OREGON: *Medical*. Portland, June 15-17. Sec., Dr. Joseph F. Wood, 509 Selling Bldg., Portland. *Basic Science*. Corvallis, July 17. Sec., State Board of Higher Education, Mr. Charles D. Byrne, University of Oregon, Eugene.

PENNSYLVANIA: Philadelphia and Pittsburgh, July 6-10. Sec., Board of Medical Education and Licensure, Dr. James A. Newpher, Education Bldg., Harrisburg.

SOUTH CAROLINA: Columbia, June 22. Sec., Dr. A. Earle Boozer, 505 Saluda Ave., Columbia.

SOUTH DAKOTA: Rapid City, July 20-21. Dir., Division of Medical Licensure, Dr. B. A. Dyar, State Board of Health, Pierre.

VERMONT: Burlington, June 16-18. Sec., Board of Medical Registration, Dr. W. Scott Nay, Underhill.

VIRGINIA: Richmond, June 17-19. Sec., Dr. J. W. Preston, 28½ Franklin Road, Roanoke.

WISCONSIN: Milwaukee, June 29-July 2. Sec., Dr. Henry J. Gramling, 2203 S. Layton Blvd., Milwaukee.

WYOMING: Cheyenne, June 7. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

NATIONAL BOARD OF MEDICAL EXAMINERS
SPECIAL BOARDS

Examinations of the National Board of Medical Examiners and Special Boards were published in THE JOURNAL, April '10, page 1291.

Montana October Report

Dr. S. A. Cooney, secretary, Montana State Board of Medical Examiners, reports the written examination held at Helena, Oct. 6-7, 1936. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Ten candidates were examined, all of whom passed.

Sixteen physicians were licensed by reciprocity and 2 physicians were licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Northwestern University Medical School.....	(1934)		83.2,
88.5, (1935) 83.7, (1936) 84.4			
Johns Hopkins University School ..			84.8
University of Minnesota Medical ..			81.5
Creighton University School of ..			79.5
Syracuse University College of ..			81.7
Jefferson Medical College of Philadelphia.....	(1930)		82.5

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
College of Medical "	"	(1931)	California

* Verification of graduation in process.

Hawaii October Examination

Dr. James A. Morgan, secretary, Board of Medical Examiners, reports the oral and written examination held in Honolulu, Oct. 12-15, 1936. The examination covered 10 subjects and included 80 questions. An average of 75 per cent was required to pass. Six candidates were examined, 2 of whom passed and 4 failed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of Illinois College of Medicine.....	(1934)		85
Hahnemann Medical Col. and Hospital of Philadelphia..	(1918)		82

School	FAILED	Year Grad.	Per Cent
Loyola University School of Medicine.....	(1930)		76,*
(1936) 75*			
Washington University School of Medicine.....	(1931)		76*
Licentiate of the Royal College of Physicians of London and Member of the Royal College of Surgeons of England	(1936)		72†

Three physicians were licensed by endorsement from July 31 through August 18 after an oral examination. The following schools were represented:

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
Tufts College Medical School.....	(1935)		N. B. M. Ex.
University of Minnesota Medical School.....	(1935)		N. B. M. Ex.
California Univ. College of Physicians and Surgeons..	(1935)		N. B. M. Ex.

* Failed in three or more subjects.
† Verification of graduation in process.

Oklahoma Reciprocity and Endorsement Report

Dr. James D. Osborn Jr., secretary, Oklahoma State Board of Medical Examiners, reports 20 physicians licensed by reciprocity and one physician licensed by endorsement at the meeting held in Oklahoma City, December 9, 1936. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
University of Arkansas School of Medicine.....	(1935)		Arkansas
College of Medica ..			California

Book Notices

Practical Examination of Personality and Behavior Disorders, Adults and Children. By Kenneth E. Appel, M.D., Ph.D., Sc.D., Assistant Professor of Psychiatry, Medical School, University of Pennsylvania, and Edward A. Strecker, M.D., A.M., Sc.D., Professor of Psychiatry, Medical School, University of Pennsylvania. Cloth. Price, \$2. Pp. 219. New York: Macmillan Company, 1936.

This volume is an outline of examination methods to be used by psychiatrists, particularly by those in training. Parts have apparently been used in training students. It is made up of two parts, the first dealing with the adult, the second with the examination of the child. In the adult section one finds a conglomeration of examination methods consisting of outlines of what to look for on mental examination and on personality study. There are presented several approaches to the same problem, such as the questions asked on mental examination, outline of information to be obtained, and examination of stuporous patients. Three types of chapters are found in this part: one, how to examine in general, consisting of essays which present quite generalized techniques; a second, giving outlines directed toward showing what specific items to look for, and a third type showing reporting forms for summarizing observations. The second part treats of child guidance examination techniques, two types of information being made available: first, outlines are presented for the results of teachers', parents' and the psychiatrist's examinations in the case; the second variety of information consists of short chapters devoted to questions concerning lying, temper tantrums and other symptoms of maladjustment, which apparently are intended as suggestions in the matter of questioning a parent of the problem child. In the middle of this group of chapters is one on enuresis in which the condition is outlined. The chapter is not like the others in style or purpose. One must agree with the authors that there is at the present time no effective outline showing a student how to conduct a psychiatric examination, but there is a good reason for this state of affairs. Psychiatry depends on individual adjustments. The technic of one leader in the field often turns out a number of disciples who use the same technic but with signally less success. Usually the adequate student develops, under personal guidance, a useful method. Then he needs no outline. Before that a written guide is misleading in that it gives him a false assurance and stereotypes him. The general instructions given in the present volume on how to interview prove that the written word is no more helpful in making a psychiatrist than a book on how to succeed might be in making a millionaire. There is at the present time only one road to become a psychiatrist and to learn psychiatry, even for the dilettante physician, and that is by watching competent psychiatrists at work and examining patients oneself under the direction and guidance of experienced mental experts. Some of the summaries in the present volume are lists of words, without background. They mean nothing and may be pernicious. There is no point to the last chapter, entitled *Psychiatric Terminology*, for it is a mere list of words where a real glossary might have meant something. The uneven style, the short chapters containing little, and the universal outlines suggest that the authors met one day in their office and decided to write a book, which they did by culling various outlines from their files without too much revision. They have forgotten the fact that psychiatry is the one medical specialty that is on trial before the profession and the public, and an influx of incompetent amateurs might cause a major setback in its development.

Atlas der Gastrophotographie. Von M. J. Heilpern, O. Porges und H. Hofmann. Paper. Price, 10 marks. Pp. 29, with 45 illustrations. Leipzig & Vienna: Franz Deuticke, 1936.

Heilpern and Porges inaugurated modern gastrophotography in 1929. Two years later two French books appeared on this subject, the authors of whom used Heilpern's apparatus and technic. The inaugurators of the method are now publishing the first German book. Every one who has expected to find decisive progress in this field will be deeply disappointed. The method seems to have reached a deadline. However, in the preface in the first time during the history of gastrophotography a fair comparison of gastroscopy is given. "Gastroscopy has been improved by the construction of the flexible tube and

now can be considered a safe method, which is easily learned. Definite areas of the stomach can be obtained more easily by the gastroscope than by the gastrophotograph. Gastroscopy has the advantage of showing the colors: this facilitates the diagnosis. However, gastrophotography still has the advantage of giving documents instead of short, gastroscopic, subjective impressions; furthermore, the local anesthesia is avoided and the gastrophotograph lies for a much shorter period in the stomach than does the gastroscope." The two latter advantages are imaginary, but the first, the possibility to present the gastric mucosa on objective documents, would be of importance if such objective documents were available. But apparently they are not. Perhaps it would not be fair to compare the numerous pictures of this book with the brilliant pictures as seen through a gastroscope. However, the comparison of these photographs with the photographs obtained through the old rigid gastroscopes (which also were unsatisfactory) shows that "blind" gastrophotography is of no avail. Only figures 23, 35, 37 and 57b correspond somewhat with certain gastroscopic pictures. A definite diagnosis would be impossible even in these cases. The pylorus never can be photographed. If one considers all the books and papers that have appeared since the invention of gastrophotographic apparatus, one can but regret the tremendous efforts of so many excellent workers, which have had such poor final results.

Mrs. Eddy Purloins from Hegel: Newly Discovered Source Reveals Amazing Plagiarisms in Science and Health. By Walter M. Haushalter. Cloth. Price, \$1.50. Pp. 126, with 2 illustrations. Boston: A. A. Beauchamp, 1936.

Mark Twain in 1907 challenged Mary Baker Eddy's authorship of *Science and Health*. The greatest humorist surmised that the source of much of *Science and Health* was some unknown author who died before his work gained public attention. Other students also have questioned Mrs. Eddy's authorship of *Science and Health*. The purpose of this small book by Walter M. Haushalter is to show that these skeptics were correct, as well as to show the source from which Mrs. Eddy "purloined" much of her famous book. In the long search for the possible original source of *Science and Health* conducted in the leading American libraries from coast to coast, every idealistic writing antedating 1870 was inspected. One day in Stoughton, Mass., some one recalled that a Mr. Minot Crane, formerly associated with Hiram Crafts, was a partner of Mrs. Eddy in an office for the practice of healing by mental means. This partnership, however, was short lived, as dissension arose. Mr. Crane lived across the street from Hiram Crafts. He was for thirty years an elder in the Baptist church and was regarded as one of the leading citizens of his community. Mrs. Eddy had lived in the Crafts home in the city of Avon and during that period Crane was a confidant of Hiram Crafts. After several conversations with Mr. Crane, he disclosed that he possessed a carefully wrapped parcel which Mr. Crafts had given him in the early eighties when he departed from Avon and Stoughton. Crafts also divulged the significance of the package and its intimate relation to Mary Baker Eddy's book *Science and Health*, hoping that some day the facts would be made public. The contents of this package were found to comprise a letter written to Hiram Crafts by Francis Lieber and also a beautifully written document of twelve pages entitled "The Metaphysical Religion of Hegel," also written by Dr. Lieber. Crane consented to dispose of this document and letter, which are reproduced in the book under review. The author places side by side for comparison numerous parts of Dr. Lieber's document and parts of *Science and Health* to show that the foundation of that philosophy, if such it may be called, was "purloined" from Lieber's philosophical treatise of Hegelian metaphysics. Hegel, the author says, was the flower of German metaphysics, whose works, comprising eighteen large volumes, were published just after his death in 1832. The present author reviews the philosophy of Hegel briefly. Francis Lieber, author of the now famous source document, likewise was born in Germany. He received the degree of doctor of philosophy at the University of Jena in 1820 and came to Boston in 1827, where he worked on the *Encyclopedia Americana* and published a translation of a French work on the revolution. He moved to New York in 1832, where he was commissioned to prepare a plan of education and instruction for Girard College, which took him to Phila-

delphia. Then he became professor of history and political economics in South Carolina College, remaining in Columbia, S. C., for more than twenty years. In 1857 he was elected to a similar professorship in Columbia College, New York, and later to the chair of political science in the law school, where he remained until his death in 1872. Lieber was a member of the Kantian Society. The Source Document bears the memorandum "Copied for Hiram Crafts, to be read before the Kantian Group, Boston Lyceum, 1866." Science and Health was published in 1875, eight years after Mrs. Eddy's stay in the Crafts home and three years after Dr. Lieber's death. In comparing these two documents the author points out that on page 85 of Dr. Lieber's document he said "Hegel's science brings to light truth and its supremacy," which statement Mrs. Eddy is said to have changed on page 293 of Science and Health to "Christian Science brings to light truth and its supremacy." A similar substitution appears in the following quotation from Lieber's document: "That spirit propagates matter or matter spirit, is morally impossible. Hegel repudiates the thought" (p. 86). Mrs. Eddy changes, the author says, these sentences to read as follows: "That spirit propagates matter or matter spirit, is morally impossible. Hegel repudiates the thought." (This is on page 264 of Science and Health.) There are many other comparisons of the two documents made here.

The addenda to this book was entitled "Mrs. Eddy's Later Plagiarisms," meaning those instances which occurred from 1895 to 1905. It is said that she took also from Carlyle, Ruskin, Amiel, Hugh Blair and Quimby. The following quotation from Mrs. Eddy's Science and Health appears on page 1 of Haushalter's book:

"No human pen nor tongue taught me the Science contained in this book, Science and Health. . . . I have found nothing in ancient or in modern systems on which to found my own, except the teachings and demonstrations of our great Master and the lives of prophets and apostles. The Bible has been my only authority. I have had no other guide in 'the straight and narrow way' of Truth." (Science and Health, pp. 110, 126.)

The Christian Science Board of Directors, disbelieving the authenticity of this book, submitted specimens of Mrs. Eddy's handwriting and specimens of Francis Lieber's handwriting to some handwriting experts, who said that neither the letter in question nor the manuscript in question nor the purported signatures were in the handwriting of Francis Lieber, and that neither the notation in question nor the purported signature of Mary Baker was in the handwriting of Mary Baker Eddy.

Trudy Instituta Mozga. Vypusk II. Pod redaktsley S. A. Sarkisova i I. N. Filimonova. Les travaux de l'Institut du Cerveau. Volume II. Cloth. Price, 18 rubles 75 kopecks. Pp. 278, with 21 illustrations and atlas containing 27 microphotographic plates. Moscow: Izdanie Gosudarstvennogo Instituta Mozga, 1936.

This volume, emanating from the Brain Institute in Moscow, presents four papers. In "Ontogenesis of the Isocortex in Man," G. I. Poliakov describes the anatomy of the isocortical part of the lamina corticalis in a human embryo whose crown-coccyx length was 90 mm. In a paper entitled "Variability of the Structure of the Cerebral Cortex of the Temporal-Basal Region of the Adult," P. S. Blinkov presents an anatomic study of ten human cerebral hemispheres. J. Shevchenko presents a paper on "The Variability of the Cerebral Cortex in Higher Anthropoids," and A. S. Chernyshev on the anatomy of "The Superior Limbic Region in Monkeys." A separate atlas consisting of eighty photomicrographs, illustrating the work of the authors, accompanies the text.

The Principles of Dental Medicine: The Medical Aspects of Dental Disease. By F. W. Broderick, M.R.C.S., L.R.C.P., L.D.S., Hon. Dental Physician to the Royal Victoria and West Hants Hospital, Bournemouth. Second edition. Cloth. Price, \$7.50. Pp. 575, with 27 illustrations. St. Louis: C. V. Mosby Company, 1936.

The author discusses the effect of the development of specialization on the practice of medicine and emphasizes the fact that the medical profession and to a still greater extent the dental profession have devoted most of their energy to the repair of the damage produced by disease rather than to the cure or prevention of disease. He follows the development of ideas in the history of medicine and points out how this development has contributed to the present condition. He discusses diathesis and emphasizes the well known clinical observation that teeth are lost either by caries or by pyorrhea and that

in general the patient with caries does not have pyorrhea and the patient with pyorrhea does not suffer with decay of the teeth; he indicates that each of these two dental conditions is associated with different types of disease in the other organs and tissues of the body. The book is stimulating and challenges thought. Although there may be some differences of opinion concerning details, such as the author's view on the vitality of the dental enamel, it is indeed encouraging to find one who is willing to review and reessay fundamental concepts in terms of the newer developments of knowledge. Broderick makes it clear that dentistry cannot be separated from the whole of medicine and that in the study of the initial deviations from normal which lead to disease there are early indications that are of great advantage to the dentist in the study of pathology. The book should have the attention of both physicians and dentists; it is certain to arouse differences of opinion that will provoke thought and discussion.

Die Nebennierenrinde: Beiträge zur experimentellen und klinischen Pathologie. Von Dr. med. Sigismund Thaddeus, Assistent der II. Med. Universitätsklinik der Charité, Berlin. Paper. Price, 11 marks. Pp. 199, with 114 illustrations. Leipzig: Georg Thieme, 1936.

The author presents a superficial review of much of the literature on the adrenal cortex and includes some recent experimental and clinical studies made in Berlin. This work is largely repetition or confirmation of original studies conducted and published elsewhere. The author's own contributions in this field are represented by eight papers (chiefly clinical) published in 1935 and 1936. The limited portion of the book concerned with clinical use of adrenal cortex extract includes treatment of conditions that are by no means proved to be associated with disturbed function of the adrenal cortex. Concerning adrenal cortex extracts, mention is made of four German proprietary products with special preference for a particular one of these, available in liquid form for parenteral administration and in tablets for oral use. As is the case with all other commercial preparations of the adrenal cortex, there is no proof that this particular product can substitute for functional loss of the cortical hormone. Especially is this true of tablets for oral administration. Yet page after page in the book is devoted to experimental and clinical observations in which the use of this particular commercial product is represented as supplying the adrenal cortex "hormone." Indeed, so striking is the frequent reference to this proprietary product that perusal of the monograph leaves an impression much like that gained from reading the publications distributed to physicians by some commercial pharmaceutical firms.

Modern Urology in Original Contributions by American Authors. Edited by Hugh Cabot, M.D., LL.D., C.M.G., Professor of Surgery, The Mayo Foundation. Volume I: General Considerations—Diseases of Penis and Urethra—Diseases of Scrotum and Testicle—Diseases of Prostate and Seminal Vesicles. Volume II: Diseases of the Bladder—Diseases of the Ureter—Diseases of the Kidney—Radiation Therapy of Tumors of the Genito-Urinary Tract. Third edition. Cloth. Price, \$20, per set. Pp. 951, with 558 illustrations; 862, with 383 illustrations. Philadelphia: Lea & Febiger, 1936.

The first edition of this book appeared about twenty years ago at a time when urology in America was a young specialty. Within the twelve years since the second edition was published, many advances have been made in the practice of urology, necessitating now the rewriting of many of the articles. The present edition has been so thoroughly revised as to constitute almost a new work. Many of the thirty-five contributors to the present two volumes are also new as such, even though they are widely known within the profession. They were selected, it is said, in order to present the widest possible representation of urologic opinion in America. They include leading diagnosticians, therapists, surgeons and pathologists in the field of urology. Emphasis is placed throughout on diagnosis and treatment. The two volumes are profusely and unusually well illustrated, mostly by original illustrations. Volume I opens with a chapter on the history of the cystoscope. Bozzani constructed in 1805 his "licht liter," with which he was able for the first time to visualize the human urethra in the living subject. This bold inventor was accused of showing an undue curiosity in investigating the concealed regions of the human body, and the medical faculty of Vienna was charged by the Austrian government to investigate his radical instrument. Twenty years later a second attempt was made to look into the urinary tract by

Segalas, who called his instrument the "speculum urethro-cystique." At about the same time Dr. John D. Fisher of Boston described an instrument originally constructed to inspect the vagina but later modified so it could be used to inspect the urethra. Twenty years passed again before there was any advance in instruments of this kind; then in 1853 Desormeaux brought forth an endoscope in which rays of light were reflected down the tube by means of mirrors, the source of which was a kerosene lamp. So this interesting history of the cystoscope goes on to the present day. Chapters on the anatomy of the genito-urinary organs follow; also on tumors of these organs, on gonorrhea, syphilis, lymphogranuloma inguinale, calculi and renal infections, including a large chapter on tuberculosis of the kidney and ureters, cystitis and other diseases. The treatment of all these conditions is adequately discussed, and those which are amenable to surgical operations especially are beautifully illustrated in detail, including a few illustrations in color. An index closes each volume. In its present form Cabot's Modern Urology is thoroughly modern and is comprehensive and authoritative.

Occupation and Health: Encyclopaedia of Hygiene, Pathology and Social Welfare. Volume I: A-H; Volume II: I-Z. International Labour Office. Cloth. Price, \$24, per set. Pp. 999, with 181 illustrations; 1,310, with 207 illustrations. Boston: World Peace Foundation; Geneva, 1930, 1934.

The increasing interest in industrial disease and in the problems in health arising from industry make especially valuable the preparation of this encyclopedia. In its development, competent industrial physicians and surgeons from all over the world have participated. The subjects concerned are classified under the headings of the work itself, the worker and the environment. Toxic substances like acetone, for example, are discussed under headings which indicate the nature of the substance, its method of preparation, its uses, the means for detecting its presence, legislation affecting the substance and the bibliographic references. Under more widely used substances, as, for example, acetylene, there are also references concerning statistics, diagnosis, symptoms and hygiene. There are extensive articles on accidents in industry, resuscitation devices, canning and food preserving, effects of industry on children and young people, and many similar topics. Particularly interesting is a discussion of industrial diseases associated with hair cutting and the work of furriers. Numerous illustrations show how industrial processes vary throughout the world. Every worker in industry and every journalist and library concerned with the effects of industrial disease will find these volumes invaluable.

Remington's Practice of Pharmacy: A Treatise on the Making, Standardizing, and Dispensing, of Official, Unofficial, and Extemporaneous Pharmaceutical Preparations, with Descriptions of Medicinal Substances, Their Properties, Uses, and Doses, and Such Other Professional Service in Connection with Community Health as the Pharmacist may be Called Upon to Render. Intended for the Use of Pharmacists and Physicians and as a Textbook for Students. By E. Fullerton Cook, P.D., Ph.M., Chairman of the Committee of Revision of the Pharmacopoeia of the United States of America, Charles H. LaWall, Ph.M., Pharm.D., Sc.D., Dean of Pharmacy, Philadelphia College of Pharmacy and Science, and others. Eighth edition. Cloth. Price, \$10. Pp. 2,162, with 702 illustrations. Philadelphia & London: J. B. Lippincott Company, 1936.

This textbook, previous editions of which have occupied important places in the pharmacists' libraries for several generations, has been revised to conform with the United States Pharmacopoeia XI, the National Formulary VI, and New and Nonofficial Remedies 1936. The scope of the volume is broad, covering thoroughly pharmaceutical knowledge and practice. It is a monumental piece of work in its field. Therapeutic uses for the individual drugs and their preparations are given. Although the therapeutic discussions are not highly critical, they are more conservative than in most books of this type. The chemistry and therapeutic use of glandular products have been revised and enlarged to conform with recent knowledge. This is a most reliable chapter. A new section on hospital pharmacy has been added, though the waning homeopathy is still represented. The book is complete with information on such topics as laws dealing with pharmacy, urinalysis, general description of the U. S. Pharmacopoeia and the National Formulary, sterilization and ampules, methods of making pills and tablets, and even such topics as ligatures and sutures. In this work Professors Cook and LaWall have the helpful aid of

more than thirty collaborators. The book also contains many illustrations; typographic errors are quite occasional. The volume is a contribution that rightly retains its place among the best in textbooks on pharmacy. It will serve well the physician who wishes to augment his library with a representative pharmaceutical work.

Medizinische Praxis: Sammlung für ärztliche Fortbildung. Herausgegeben von Prof. Dr. L. R. Grote, leitender Arzt der medizinischen Klinik des Rudolf-Hess-Krankenhauses Dresden, Prof. Dr. A. Fromme, Direktor der chirurgischen Abteilung des Stadtkrankenhauses Dresden-Friedrichstadt, und Prof. Dr. K. Warnekros, Direktor der staatlichen Frauenklinik zu Dresden. Band XIV: Elektrokardiographie für die ärztliche Praxis. 15 Vorlesungen zur Einführung in die elektrische Untersuchungsmethode des Herzens und ihre praktischen Ergebnisse bei rhythmischem und arrhythmischem Herzschlag. Von Prof. Dr. Erich Boden. Third edition. Paper. Price, 10 marks. Pp. 187, with 101 illustrations. Dresden & Leipzig: Theodor Steinkopff, 1936.

This edition has been increased in size by some thirty pages and is much better assembled than the preceding edition. However, in comparison with other books both in German and in English dealing with the subject, this one is somewhat inferior. Not much is said about the precordial lead in infarction of the heart. The terminology with regard to ventricular extrasystoles and bundle branch block used by the author is no longer followed. Many of the electrocardiograms are touched up, and the illustrations presented to cover the various subdivisions might have been improved. Nevertheless, the diagrams with which this booklet is profusely illustrated should be stimulating not only to beginning students and medical practitioners but also to persons well versed in the subject.

Pathology. By Eugene C. Piette, M.D., Pathologist and Director of the Clinical Laboratories of the West Suburban Hospital, Oak Park, Illinois. Second edition. Fabrikoid. Price, \$1.75. Pp. 263, with 60 illustrations. Philadelphia: F. A. Davis Company, 1936.

This little book was written to provide training for nurses in a few elementary principles of pathology. The author has attempted to present briefly a few of the most important problems. The list of questions at the end of each chapter helps to facilitate comprehension. Considerable emphasis is placed on the handling of specimens for laboratory work. The book evidences a sincere attempt to introduce the subject of pathology to nurses in training in as simple a manner as the short time at their disposal permits. It should fill its purpose admirably.

Plastic Surgery of the Nose. By J. Eastman Sheehan. Second edition. Cloth. Price, \$9. Pp. 186, with 235 illustrations. New York & London: Paul B. Hoeber, Inc., 1936.

This edition is more compact, more graphic and more practical than the first. The deformities are better classified and their correction described as problems of everyday practice. The author recognizes the fact that nasal deformities usually involve more than one aspect of the nose and that it is necessary to combine several procedures in order to regain the normal. His chapter on typical and distinctive operations therefore in the first part of the book leads the way to a better understanding of the classified corrections that are taken up in the succeeding chapters. Several of the author's procedures differ somewhat from the Joseph technic, which most rhinoplastic surgeons have adopted, but all of them are based on sound surgical principles. The rationale of his technic is clearly explained and numerous illustrations bring home forcibly the important details. His description of the costal cartilage implant for saddle nose is still preeminent. The book is neither too long nor too involved, which should recommend it to surgeons in general as well as to rhinologists and oral surgeons.

Veröffentlichungen aus der Konstitutions- und Wehrpathologie. Herausgegeben von L. Aschoff, W. Ceelen, W. Koch und P. Schürmann. Geleitet von W. Koch. Heft 38. Band IX, Heft 1: Renaler Zwerzwuchs. Von Alfred Welz. Paper. Price, 51 marks. Pp. 56, with 13 illustrations. Jena: Gustav Fischer, 1936.

This monograph on renal dwarfism develops the subject from the standpoint of previous cases described in the literature with especial emphasis on the clinical picture, the pathologic anatomy and the pathologic physiology. Two cases studied by the author are carefully described. Eighty-six references are given. The author goes into great detail with regard to the relationship of the bone changes of so-called renal rickets. He also

discusses the significance of blood chemistry with particular emphasis on the changed calcium: phosphorus ratio. He concludes that the dwarfism is due in all probability to the development of growth-restraining substances arising in the body because of the increasing acidosis and toxicosis resulting from so-called chronic interstitial nephritis. He suggests the possibility that in this process certain hormones are destroyed.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Acts: Right of Examining Board to Redetermine Qualifications of Applicant.—William V. Dubin in 1925 was refused permission to take the examination for a license to practice medicine in Wisconsin because he lacked the statutory qualifications. The following year he again applied for an examination, presenting to the board a diploma from the Maximilian University of Würzburg, Germany, but, because the foreign credentials were neither translated nor verified, an examination was refused. In 1928 and 1929 Dubin's applications for permission to take the examination were denied, the board having had notice that the foreign diploma had been revoked. In June 1930 Dubin presented a statement from the American consulate certifying that the revocation of the diploma had been rescinded and Dubin was permitted to take the examination. He failed. Subsequently he was examined on six other occasions and failed each time. Following the last attempt, in 1934, the board permitted Dubin to take a special examination in one subject after he had signed an agreement that the board would not grade the examination paper until it had further satisfied itself concerning his qualifications. The agreement specified that the board would make its determination "by the time or at the time of the regular meeting of said board in January, 1935." At that meeting the board passed a resolution refusing to grade the examination paper and to issue a license for the reason that "said Dubin has not completed the required medical studies to entitle him to practice medicine and surgery, or to graduate from a reputable medical college, and is not intellectually, morally or professionally qualified to practice medicine and surgery in the state of Wisconsin." Thereafter Dubin sought a writ of mandamus to compel the board of medical examiners to grade his paper and to issue to him a license to practice in Wisconsin. The trial court denied the petition and Dubin appealed to the Supreme Court of Wisconsin.

Dubin first contended that the agreement exacted from him as a condition to his taking the special examination was discriminatory and beyond the power of the board. The wisdom of this administrative procedure, said the court, may well be questioned, but it could hardly be condemned on either of the grounds assigned. Since Dubin was not entitled under the rules of the board to a special examination, the granting of it was a concession to him, and if there was discrimination, it was in his favor, and there was no reason, the court said, why the board might not condition this concession on a recanvass of the facts bearing on Dubin's qualifications. The medical practice act provided that the board must find Dubin qualified before it could issue a license to him. The term "qualified" has reference to the moral, professional, educational and intellectual qualifications of the applicant, and the board, even after accepting as *prima facie* satisfactory a showing by an applicant on any of these matters, may reinvestigate and come to a different conclusion provided the ultimate judgment is not arbitrary or capricious.

The ultimate question in the case, said the court, was whether the action of the board was arbitrary and capricious. The record showed that Dubin attended Marquette University School of Medicine during the school year 1918-1919, and that because of his poor scholastic record he was advised to repeat the work of the first year. During the summer sessions of 1919 and 1920 he earned some credits in the University of Wisconsin Medical School and was permitted in the fall of 1920 to reenter

Marquette and take second year work on probation. He was dismissed from that university in February 1921 for dishonesty in examination and received no credit for the work done during the fall. Dubin claimed to have matriculated in Hahnemann Medical College in September 1921 as a third year student, but the evidence showed that he was admitted as a special student taking freshman work and that in October 1922 he was declined the privilege of further registration because of poor scholarship. He then matriculated at the St. Louis College of Physicians and Surgeons, "a class C school and rated a diploma mill by the board." Although he claimed to have graduated from that school, a supposedly complete list of graduates of the year of his claimed graduation did not include his name. While Dubin claimed to have entered the University of Freiburg in Germany some time in February 1925 and to have pursued there all the necessary medical courses, advices from that school indicated that he entered the summer session of 1925 and merely took some relatively unimportant laboratory courses. Although Dubin claimed to have pursued medical studies at Maximilian University at Würzburg, he never matriculated there. By special dispensation he was permitted to present a doctor's thesis and take an examination at the school and was apparently granted a degree. Thus, observed the court, the school which gave the degree had had no supervision over the medical training of Dubin and gave the degree because of his preliminary work at other schools. This degree was later revoked by the Maximilian University because it had been "ascertained that the candidate does not possess the necessary preliminary education and that the conferring of the degree is based on incorrect statements and presuppositions." In 1930, after representations made to the ministry of state through the office of the American consul, the action revoking the degree was rescinded "because there was no guilt on Dubin's part." It will be noted, said the court, that the action rescinding the revocation of the degree made no finding that the original action of revocation was founded on mistake. A refusal to grant a license on the foregoing facts cannot, said the court, be the basis for a claim of arbitrary conduct by the board.

Dubin next contended that he had no hearing or opportunity to be heard when the board finally acted on his case. This contention, said the court, was without merit. The action was taken by the board at a regular meeting. The time of such meeting was regulated by statute. Whatever materiality the agreement signed by Dubin might have, it was clear that it notified him that action on his preliminary training and general qualifications would be taken at the regular meeting of the board in January 1935. This was a sufficient notice, and Dubin could have appeared and presented to such meeting any matters germane to the inquiry.

The Supreme Court concluded, therefore, that the trial court correctly held that Dubin was not entitled to a writ of mandamus.—*State ex rel. Dubin v. Wisconsin State Board of Medical Examiners (Wis.)*, 268 N. W. 116.

Pharmacy Practice Acts: Sale of Aspirin (Acetylsalicylic Acid) by Grocer.—The pharmacy practice act of Montana declares it to be unlawful, with certain exceptions not here pertinent, for any person other than a registered pharmacist to sell at retail any drug other than a "patent" or proprietary medicine in the original package. The defendant, a retail grocer, was convicted of violating this act under a complaint charging him with selling an original package of aspirin. He thereupon appealed to the Supreme Court of Montana.

It was testified at the trial, said the court, that aspirin is a drug and it was shown that aspirin is usually held not to be a proprietary or "patent" medicine within the meaning of acts similar to the one here involved. The question before the court was the constitutionality of the limitation to pharmacists of the sale of drugs in manufacturer's original packages. All decisions agree, said the court, on the validity of statutes licensing pharmacists and prohibiting the sale by persons other than licensed pharmacists of drugs and medicines which are compounded by the vender or sold by him in any manner other than in the original package of the manufacturer. A diversity of opinion arises, however, concerning the constitutionality of

acts with reference to medicine and drugs sold in the original package of the manufacturer. The arguments advanced to sustain the constitutionality of such acts did not appeal to the Supreme Court of Montana. On the other hand, the court quoted extensively, with apparent approval, from *State v. Wood*, 51 S. D. 485, 215 N. W. 487, decided by the Supreme Court of South Dakota and involving the sale of a proprietary medicine. Said that court, in part:

Both the briefs of appellant and of the amicus curiae seem to assume that restricting the sale of such medicines to registered pharmacists will protect the public from all the ills that might result from unrestricted sale. But they do not point out how the public are protected. It is suggested that a pharmacist, to obtain his license, must be of good moral character, and that would protect the public from verbal misbranding, fraud, and dangerous medicines; but why restrict the sale to pharmacists only, when there are many other men of good moral character? If moral character is a sufficient guaranty, the statute might require vendors to be men of good moral character; but there can be no reason for requiring them to be druggists. Again, it is urged that pharmacy is a profession with a code of ethics; but pharmacy is not the only profession with a code of ethics. It is argued that pharmacists have knowledge of the effect of medicines they sell; this is no doubt some protection against accidental injury resulting from ignorance, but it is not plain that pharmacists do know the ingredients of patent and proprietary medicines, or that they are required to use or possess any knowledge in making a sale of such medicines. If one has a doctor's prescription filled at a drug store, he buys not the medicine alone, but the druggist's knowledge and skill in dispensing it; but if he were to buy Watkins' Pain-Oleum at the drug store, what more would he buy than if he bought elsewhere?

It does not seem that merely selling an article, though that article be medicine, can be classed as the practice of a learned profession. It would seem that the practice of a profession ought to call in use the learning peculiar to the profession. . . . It would seem to be an unreasonable exercise of the police power to limit sales to the profession, without requiring anything of the profession to safeguard the public health.

Taking into consideration, said the Supreme Court of Montana, that the pharmacy practice act absolves pharmacists from all responsibility as to the purity, strength and quality of drugs or medicines which are sold in the manufacturer's original packages, no justifiable reason exists for arriving at the conclusion that to limit the sale of such articles exclusively to pharmacists can in any way tend to protect or preserve the public health. The court therefore held the pharmacy practice act unconstitutional so far as it restricted to pharmacists the sale of drugs and medicines sold in the manufacturer's original packages. The judgment of the trial court was reversed and the cause remanded with direction to dismiss the complaint.—*State v. Stephens (Mont.)*, 59 P. (2d) 54.

Malpractice: Radium Left in Patient; Accrual of Right of Action.—The defendant, a physician, inserted ten "radium beads" in the uterus of the plaintiff's wife, Jan. 18, 1929, for a condition diagnosed as cancerous. According to the record, one of these "beads" was supposed to be removed each succeeding day by means of a string attached to it. At the expiration of the ten-day period the defendant advised the plaintiff and his wife that all the "beads" had been removed. Despite this assurance, it was alleged, four "beads" were left in the uterus. They severely burned the plaintiff's wife, migrating to the intestine. Peritonitis set in about March 1, 1935, resulting in the death of the wife on March 18. The plaintiff thereupon sued the defendant for damages for the death of his wife. The trial court overruled a demurrer filed by the defendant to the petition and he appealed to the Supreme Court of Kansas.

The only question before the Supreme Court was whether or not the action was barred by the two-year statute of limitations. The defendant contended that the right of action accrued when, at the expiration of the ten-day period, he failed to remove the last "bead." The suit was barred by the statute of limitations, said the Supreme Court. If a plaintiff seeks to recover damages from a physician on account of alleged malpractice, the action sounds in tort and the two-year statute of limitations applies and is not tolled by concealment of the tort by the physician. The right of action accrues when the tort is committed. In an action based on wrongful death where the statute of limitations had run against an action by the injured party, an action by his personal representatives under the wrongful death statute is also barred. The judgment of the trial court overruling the defendant's demurrer was therefore reversed.—*Graham v. Updegraph (Kan.)*, 58 P. (2d) 475.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Prevention and Control of Puerperal Infection Due to Beta Hemolytic Streptococcus.—Douglas states that hemolytic streptococcus infections are nearly always exogenous. The organisms are brought to the genital tract by the attendants or somewhat less frequently by the patient herself. Ascending infections, which represent a large percentage of the total incidence of the disease, are caused by organisms present in the vagina at the onset of labor, the chief example being anaerobic streptococcus infections. They may become invasive during labor or the puerperium because of changes either in the general condition of the patient or in the tissues of the genital tract initiated by labor and the puerperium. Contaminated material from the rectum can be carried into the vagina, during vaginal examinations or through operative intervention. In instances of infection arising in this manner, cultures of the lochia may yield such organisms as the colon bacillus, anaerobic gas bacilli (Welch bacillus) and various types of the nonhemolytic streptococcus. Contaminated urine may spontaneously carry the infecting organisms, usually members of the colon group, directly into the vagina. Organisms due to ineffective sterilization or disinfection are present on the hands of the obstetri-

Angina Pectoris and Pernicious Anemia.—Stalker reports a case of angina pectoris and hyperchromic macrocytic anemia (with aortic stenosis and regurgitation, coronary sclerosis, cardiac asthma and idiosyncrasy for morphine), with a summary of the literature bearing on this symptom complex. The anginal pains were relieved with glyceryl trinitrate but were less frequent when the blood picture approximated the normal or at least improved when a higher blood count was obtained. The theory has been propounded that anoxemia is a factor initiating angina, and it is conceivable that, in pernicious anemia, blood of poor quality might readily aid in the development of an anginal spell on slight provocation. Because the age period of these two diseases is approximately the same it may be a natural occurrence that they are found together in the same patient. It was felt by one investigator that patients with anemia do not often develop angina because of their general easy fatigue, which causes them to stop short of the danger point. But, as most patients with pernicious anemia do not have angina, the anemia alone cannot be a primary cause. Again, the pathologic changes in the heart muscle in pernicious anemia have been thought to be due to lack of oxygen from the fact that the coronary circulation is taxed to the upper limit, comparable to the effects of strenuous work. In general the consensus has been that there were no diagnostic abnormalities in the electrocardiograms and what changes were noted could be traced to a coincident cardiosclerosis.

Trichlorethylene in Preventing Attacks of Angina Pectoris.—At the suggestion of David Bryce, Love investigated the effect that trichlorethylene may have in preventing attacks of angina pectoris. Twenty-seven patients were given from two to four, usually three, inhalations of trichlorethylene daily. Sealed frangible glass ampules of 1 cc. are crushed in a handkerchief. The first inhalation has always been taken in the presence of a physician so that the immediate effect might be noted and the patient reassured, if alarmed. Thereafter, patients are advised to take the drug either while reclining or sitting, for marked lightheadedness often occurs and occasionally there is a brief loss of consciousness. The treatment is continued for three weeks. If no therapeutic effect has been achieved in this time, the use of trichlorethylene has been discontinued and the method considered ineffective. Should the treatment prove effective, the number of inhalations is reduced in each individual to the minimum consistent with adequate relief of symptoms. Lightheadedness lasts only a few moments and leaves the patient mentally clear. When the patient has been nervous and irritable and sleep has been restless, well marked sedation, loss of irritability and quiet sleep have usually followed the use of the drug. Six patients have been given trichlorethylene during immediate attacks of pain due to coronary thrombosis. In three of four cases seen within twelve hours of the onset of coronary thrombosis trichlorethylene afford relief from pain, proving more useful than morphine in one case and less useful in one case. In one case trichlorethylene was ineffective. In two more cases relief of pain followed the use of this drug but, because of the length of time elapsing from the occurrence

of the thrombosis to the initiation of inhalation treatment, disappearance of the pain cannot with certainty be attributed to the treatment. It is possible that trichlorethylene was more effective than morphine in one of these cases. When successfully used, it had the advantage over morphine of not causing constipation. Of the remaining twenty-one patients, eighteen had either arteriosclerosis or arteriosclerosis and hypertension combined. All these patients presented angina pectoris as a symptom of their disease. Of these twenty-one patients anginal seizures were prevented completely by the inhalations in eight; they were definitely diminished in frequency and severity in eight and moderately diminished in one. Four patients received no benefit from the inhalations. In seven patients it was noted that the pain recurred as severely as formerly whenever the inhalations were discontinued, the time elapsing before its recurrence varying from twenty-four hours to several weeks. While pure trichlorethylene in the recommended dosage does not seem to be toxic, it should be used with some caution owing to the reported cases of industrial poisoning due to this agent.

Heat Regulation in Chronic Encephalitis.—Finkelman and Stephens compared the increase in the oxygen consumption (metabolism or heat production) and the ability to maintain the normal body temperature in patients with chronic encephalitis and in normal subjects on exposure to cold. There was a greater gain in oxygen consumption in normal subjects on exposure to cold than in patients with chronic encephalitis. The least gain in oxygen consumption occurred in patients with chronic encephalitis treated with atropine. More marked differences were noted in the body temperatures on exposure to cold. Eight of the normal subjects showed an increase of temperature on exposure (overcompensation), whereas only one of the patients with chronic encephalitis, who was receiving treatment with atropine, reacted with an elevation of temperature. All the other patients reacted with a lowering of body temperature on exposure. There was a greater drop in the temperature of the normal subjects after the bath. This reaction did not occur, as a rule, in patients with chronic encephalitis, as after the bath the oral temperature did not drop further but rose instead. It is probable that the normal vasodilatation or reactive hyperemia did not occur in patients with chronic encephalitis. There was a greater loss in temperature as well as a lower oxygen consumption rate in the patients with chronic encephalitis while they were treated with atropine than after the use of atropine had been discontinued. The basal metabolic rate in patients with chronic encephalitis was higher than that in the normal subjects (average, 25.25 per cent as compared with —2.7 per cent). With treatment with atropine the metabolic rate in cases of chronic encephalitis was reduced, although it was still above normal. There was no correlation between the rigidity and tremors and any of the observations noted.

Trichinosis Involving Nervous System.—Most and Abeles epitomize the literature relating to the clinical manifestations and neuropathologic changes in trichinosis of the nervous

system. They cite two additional cases of trichinosis in which the mental and neurologic signs predominated. The mental picture was that of mild acute encephalitis in one case and of a chronic encephalopathic process with Korsakoff's features in the other. There were no clinical signs of meningeal irritation. Neither trichinae nor alterations in the number of cells and the globulin content were observed in the spinal fluid in either case. Focal neuralgic signs in the form of hemiparesis were seen in one case. Massive anasarca and other changes simulating the wet form of beriberi were observed in the patient who recovered, and failure of eosinophilia to develop was observed in the patient whose illness terminated fatally. A pathologic study including the nervous system was made in one case. Larvae of *Trichinella spiralis* were demonstrated in the brain substance. The pathologic changes seen in the brain were in the nature of widespread acute nonsuppurative encephalitis. The characteristic changes were the disseminated nodules, with and without parasites, and the perivascular and meningeal infiltrations, as well as the degenerative changes seen in most toxic conditions of considerable duration.

Trichlorethylene in Treatment of Migraine.—Because of the supposed association between trichlorethylene and the trigeminal nerve and because of the preponderant innervation of the dura by the trigeminal nerve, Rubinstein deemed it advisable to use this drug in the treatment of six patients having migraine. It appears that trichlorethylene is a valuable adjunct in the treatment of migraine. This opinion is based on the fact that during the year of its trial on the six patients consistently beneficial results were obtained. The use of the drug is not to serve as a substitute for a painstaking survey, since it is questioned whether the striking results obtained in case 1 would have occurred if the patient had not simultaneously been treated for the defects in personality and endocrine function. The probability concerning the mode of action of the drug is certainly against its direct influence on the underlying cause of the condition, since in accordance with the theories concerning the etiology of migraine it is almost certain that trichlorethylene fails to strike at the root of the difficulty.

Acacia in Treatment of Nephritic Edema.—From his review of the limited literature on the subject and from his experience with a case, it seems to Boone that acacia may eventually prove to be of definite value in the treatment of hypoproteinemic edema that fails to respond to the usual measures. Its effect in greatly increasing the blood volume would seem to contraindicate its use in patients with any evidence of cardiovascular disease. This contraindication would probably apply to the hypoproteinemic edema of beriberi because of the myocardial weakness that is so frequently a feature of that disease. If a history of allergy is obtained, the drug should be given most cautiously, and careful skin tests should be done before each injection, whether the patient is allergic or not. The solution should be carefully prepared and freshly made up, unless it is prepared with sodium chloride, and should be given slowly. The preparation of the solution is a difficult and tedious procedure, and some authors have used a 30 per cent solution in 100 cc. ampules marketed by a large pharmaceutical house. Some investigators have felt that the acacia appears to exert a curative effect on the renal lesion, but the author was unable to observe that acacia had any beneficial effect other than the removal of edema and its attendant symptoms.

Adenomas and Rectocolonic Carcinomas.—Yeomans believes that sigmoidoscopy should be done in every patient having symptoms referable to the colon or rectum, such as hemorrhoids, rectal bleeding, pain or discomfort, sciatica, persistent diarrhea, progressive constipation or a feeling of incomplete relief after evacuation. Any growth, however small and innocent in appearance, should be destroyed by fulguration or, if excised, submitted to a competent tumor pathologist. In his thirty-five cases of solitary adenomas, thirteen proved to be malignant. Prompt removal of an adenoma is the only guaranty against its later change into adenocarcinoma. A follow-up examination at intervals of six months for three years should be made. Multiple polyposis and adenomatosis coli are grave conditions requiring major surgery for relief. Convincing proof is presented of malignant degeneration, frequently multicentric, in both groups of disseminated growths. Adenomas develop particularly in the cancer age and their number more closely approaches the number of cancers in the sigmoid and rectum than elsewhere in the gastro-intestinal tract. Doubtless car-

cino-ma of the colon and rectum is frequently mediated through an adenoma, but it cannot be affirmed as yet that all recto-colonic cancers originate from adenomas.

Diabetic Arteriosclerosis.—By injecting metallic mercury into the popliteal artery and taking roentgenograms of the entire leg below the knee, Henderson has studied the gross pathologic changes in the arterial channels of seven diabetic legs which have come to amputation. The mercury was introduced at approximately systolic blood pressure, so that a rough approximation of physiologic conditions was produced. As metallic mercury will not pass through capillaries, a clear picture of the available arterial channels in a given leg can be obtained. After a study of the roentgenograms the leg was dissected at strategic points and the arteries were studied directly. The order of involvement of the arteries seemed to be posterior tibial, peroneal and anterior tibial. The extent of the arterial changes corresponds much more to the duration of the diabetes than it does to the age of the patient. It seems possible that diabetic arteriosclerosis starts as a patchy affair. It may sometimes occlude a major vessel so rapidly that adequate collateral circulation cannot develop to prevent gangrene. It may sometimes progress slowly, accompanied by the development of good collateral circulation, and eventually involve most of the major vessels in a diffuse process. At this stage it either resembles or is identical with nondiabetic or senile arteriosclerosis. In the slowly developing cases the collateral vessels, though never able to deliver a normally rich supply of arterial blood to the part, seem often to be sufficient to keep the patient symptom free or to diminish only slightly his activity and comfort if infection is avoided. Infection seems to be the precipitating factor.

Circular Lesion of Pulmonary Tuberculosis.—Birkelo and Kasper base their dissertation on sixty cases of pulmonary tuberculosis selected on the basis of their circular outline. Most of these cases have been observed for more than a year, some for periods of from five to six years. While some of the circular lesions were observed to develop from originally diffuse tuberculous infiltration, others were circular at the time of the

first observation. A small group includes those which appear to represent the final stage of a primary or childhood type of infiltration. Contrary to the belief of previous observers, it is felt that some circular lesions develop from first infection. According to the authors' observations, the circular lesions may be divided into three groups. The first group includes the lesions that have been found to develop from diffuse infiltration. Such lesions are not entirely stationary and may undergo excavation. Most of them, however, show a tendency to become smaller. The second group includes the lesions that are definitely circular when first discovered. They may be single or multiple but in most instances are solitary lesions varying in size from 0.5 to 3 cm. in diameter. Most of them are of uniform density and well defined in outline; they are definitely in the parenchyma. Occasionally they excavate and may cause a spread of the tuberculous disease. These lesions remain stationary for months and years and probably represent the well encapsulated type, which is least likely to become active. The third group includes the receding stage of the childhood type of infiltration. At first the lesions of this group were found to be definitely circular; later they retrogressed without any collapse therapy. It would appear that the lesions of the second group require only periodic check up. In the event that excavation should begin, the indication would be for some therapeutic intervention. Three cases showed evidence of excavation, while thirty-six remained inactive. The lesions in the first group represent incomplete healing with the possibility of incomplete encapsulation. Since the majority of sixteen cases showed retrogression, it would be justifiable to conclude that their outlook for satisfactory recovery would be good and that one might expect eventual disappearance of the lesion or complete encapsulation. No additional suggestions can be advanced for the lesions in the third group except to emphasize that continued observation of the lesions is a necessity.

Roentgen Evidence of Metastatic Malignancy in Bone.

—Several years ago, following a necropsy on an extremely emaciated individual, Snure and Maner reviewed the roentgenograms of his lumbar spine, which had indicated changes in the fifth lumbar body alone. Necropsy showed macroscopic evidence of metastatic malignant changes throughout most of the vertebral bodies. Microscopic examination proved that tumor cells had replaced most of the marrow cells without destroying the trabeculae of the spongiosa; however, there were several areas, about 1 cm. in diameter, where the trabeculae were destroyed that could not be demonstrated on the roentgenogram. Following this observation they removed a V-shaped section of bone from the vertebral bodies of all patients dying of a malignant condition when necropsy was permitted. To avoid distortion due to the spine-film distance or to the superimposed shadows, they saved the spinal column lengthwise in the sagittal plane and placed one half directly on the film holder; even under these conditions the larger areas of destruction were not demonstrable on the roentgenogram. It is surprising how frequently metastatic malignant change is present in the vertebrae without clinical signs and without evidence on roentgenograms that have excellent detail and quality. By merely taking a wedge of bone about 0.5 cm. in thickness from the lumbar vertebrae they found several cases of malignant metastatic growths originating from primary carcinoma of the liver, tongue, stomach, gallbladder, urinary bladder, pancreas, rectum and other organs supposed to metastasize but rarely to the osseous structures. The largest number of metastases to the vertebrae was secondary to breast and prostatic carcinoma. The best method of study would be that suggested by Fraenkel of sectioning and roentgenographing all bones of the body.

Pentobarbital Sodium for Roentgen Nausea and Vomiting.—Their careful study of 175 patients who had received pentobarbital sodium, in all of whom nausea and vomiting was expected to occur after treatment, revealed that 61.1 per cent received complete relief from roentgen sickness, 18.3 per cent had only moderate nausea, 10.9 per cent had nausea with a very slight amount of vomiting, and 9.7 per cent obtained no relief. Popp and Binger found that the administration of 3 grains (0.2 Gm.) of pentobarbital sodium as a suppository immediately following a session of treatment was most successful. Since pentobarbital sodium is easily available, inexpensive, easily

administered, and in their experience without harmful effects, they feel that its use in controlling roentgen nausea and vomiting is definitely indicated.

Bone Changes in Sickle Cell Anemia.—Diggs and his associates attempt to summarize the known facts concerning the pathology and roentgen appearance of bones in sickle cell anemia based on the recorded observations of other investigators and observations made at the John Gaston Hospital. Thirty-nine Negroes with active and severe sickle cell anemia have been studied clinically. Eight necropsies have been performed. In each necropsy the bone marrow was examined, in five the skull was examined and in three one or more long bones were sectioned. The pathologic material has been supplemented by microscopic sections of bones. The bones of thirty Negroes with sickle cell anemia have been studied roentgenologically, the total number of roentgenograms being 259. For controls the files of the fracture clinic were used. The gross microscopic and roentgen appearance of the bones in sickle cell anemia indicates that the bone marrow is primarily involved. Two factors appear to be working in opposite directions: the hyperplastic marrow tends to increase its volume at the expense of bone and the sclerosing factors tend to replace the marrow and to substitute in its place osteoid tissue or new bone. The excessive and abnormal growth activity of the marrow has, as a rule, no significant effect on the bony cage within which it is confined, and such effects as it does have are maximal in the bones that are normally engaged in blood cell formation, such as the skull and cancellous bones of the trunk. In these bones osteoporosis is dominant. In the long bones in which normal hematopoiesis does not occur, sclerosis is dominant. In the most distal bones of the hands and feet in which marrow is absent the changes are minimal. The combination of marrow expanding and marrow replacing processes leads, if the patient lives long enough, to gross anatomic derangements in the bone structure.

Inguinal Hernia and Traumatic Perforation of Intestine.—Aird discusses the relation that inguinal hernia bears to traumatic perforation of the intestine, as the result of direct injury to the hernia or abdominal wall or indirectly as the result of excessive muscular effort. When the causative violence has been applied directly to the hernia, the intestine is ruptured as it lies unprotected in the hernial sac. In injury by a force applied to a point on the abdominal wall remote from the hernia it can be presumed that a fixed loop of intestine is more liable to injury than is a freely movable loop that can be dislodged in safety by a force applied to the abdomen. Ruptures of the intestine resulting from violent hyperextension of the trunk, without direct injury to the abdomen, are still less easily explained. To account for these cases, Bunge points out that any sudden rise of intra-abdominal pressure is invariably associated with a coincident rise in intra-intestinal pressure. In the normal abdomen such a rise is of little consequence, since the pressure within the intestine is equal to the pressure around it. If at the time of sudden elevation of intra-abdominal pressure a loop of intestine overlies the mouth of a hernial sac, and a rise of pressure consequently occurs in that intestinal loop, the loop lacks the support of the intra-abdominal pressure at a localized point on its surface, protrudes downward into the sac in which no rise of pressure has occurred, and bursts at that unsupported point. When the intra-abdominal pressure falls again, the ruptured loop moves away from the abdominal ring and discharges its content through the perforation to give a general peritonitis. Ingenious as the theory is, its complexity is a bar to its unqualified acceptance. It would be simpler to explain these cases by overstretching of a loop of intestine, fixed at one end at the ileocecal or duodenojejunal junction and gripped at the other by a contraction of the abdominal muscles around the hernial orifice. A loop of intestine lying within a hernial sac may be injured by violence applied directly to the hernial swelling—the pressure of an ill adjusted truss, or too vigorous attempts to relieve an incarceration. Ruptures of the intestine caused by violence to the abdomen appear to be due to the application of the traumatic force to a doubly fixed and immovable intestinal loop. Ruptures by muscular violence are most simply explained by the overstretching of an intestinal loop between the ileocecal (or duodenojejunal) junction and the abdominal inguinal ring, and distraction of these points of fixation from each other by violent hyperextension of the trunk.

Toxin Formation in Burned Tissues.—In their experiments on rabbits, Wilson and his colleagues demonstrated that edema fluid extracted from a burned area is toxic to healthy animals of the same species. By injecting edema fluid itself,

they avoided fallacies connected with methods of chemical extraction. The development of toxicity was slow, probably steady and progressive, up to forty-eight hours at least. Fluid at four hours after injury was not toxic. Clearly the toxic principles were not formed immediately by the action of heat. It was seen that toxic substances could be formed in edema fluid by enzyme action after organisms had been removed by filtering. Therefore it seemed justifiable to conclude that autolysis of injured tissue was the mechanism of toxin elaboration. The actions of edema fluid indicated that more than one toxic substance was present. Some samples had a rapidly lethal, apparently neurotoxic, action which was entirely absent from others. Samples which caused death within a few hours did so by virtue of some component which had many points of community with histamine and other capillary poisons. When edema fluid caused death after a considerable number of hours, there was sometimes little to indicate its mode of action; the chief, though not invariable, effect was to produce degenerative changes in the liver cells. The toxic bodies were associated mainly with the globulin fraction, though the albumin fraction was only slightly less implicated, and thus were brought into the category of protein derivatives. The burned animals were in most instances very little affected by the injury during the period of survival allowed; i. e., forty-eight hours. Since the burned area was of limited extent and the development of toxicity was gradual, the quantity of toxin absorbed during the period of survival would be small. The capacity of animals to survive repeated small doses of toxin was proved in experiments on attempted immunization. A comparison of the toxic effects in animals of injected edema fluid with the clinical condition of acute toxemia is of special interest. In many respects there is a marked similarity; the resemblance is perhaps strongest in the postmortem changes, because the striking and constant feature of fatal toxemia is necrosis and fatty degeneration of the liver cells in the centers of the lobules. Even without these points of similarity, the demonstration of toxin formation in burned areas is in itself suggestive that the action of circulating toxins may play an important part in the systemic disturbances of burns. Taken in conjunction with evidence that in human cases increased concentration of the blood, early bacterial infection and changes in blood chemistry are not essential causes of toxemia, the results of the investigation seem of particular significance.

British Medical Journal, London

1: 153-202 (Jan. 23) 1937

Variations of Weight During Pregnancy.—Evans declares that it is universally agreed that there is very little variation in weight during the first trimester, some patients losing a little and others gaining, depending probably on the ease with which the body adjusts itself to the presence of the ovum. The increase that occurs must therefore take place during the last six months. The average monthly gain during the second and third trimesters should be between 2 and 4 pounds (0.9-1.8 Kg.) and the total gain between 16 and 18 pounds (7.3-8.2 Kg.). If the gain is greater, the patient should be questioned carefully and be examined in order to find, if possible, the cause of the discrepancy. In the 211 cases under consideration the average increase in weight of a potential toxemic patient was definitely more than that of a normal patient, but it was not sufficient to be of real clinical value, since the 4.3 pounds (2 Kg.) that was found to be the average monthly gain of the toxemic patients was as a rule gained by the normal women during one of their later months. If, however, the patient has a monthly gain of from 4 to 5 pounds (1.8-2.3 Kg.) in two or more consecutive months, it should be regarded as abnormal; dietetic errors, if present, should be rectified and a stricter supervision undertaken. On the other hand, a sudden marked rise in weight during one month is of great help in foretelling a toxemia. If the patient showed a monthly gain of 8 pounds (3.6 Kg.) or

more, there was a 63 per cent chance of her developing a toxemia and, following a 6 to 8 pound (2.7-3.6 Kg.) gain, a 50 per cent chance. It would appear, therefore, that it is the sudden abnormal increase in weight rather than the gradual gain which is of importance in detecting an incipient toxemia. This abnormal gain is as a rule an earlier sign than a raised blood pressure, but occasionally the latter is the first indication. Therefore ideal antepartum supervision should include the taking of the weight and blood pressure each month during the second trimester, with more frequent observations during the last trimester, permitting a diagnosis of toxemia of pregnancy before albuminuria appears. Treatment could then be given and the percentage of the maternal mortality due to the toxemias of pregnancy should be materially reduced. In this way a certain number of the toxemic cases may be avoided; if not avoided, with appropriate and early treatment most of the cases would be less severe.

The Active Agent in Prontosil Therapy.—Fuller states that in normal animals 35 per cent of the injected sulfanilamide and 49 per cent of the soluble prontosil are not accounted for. A part of these drugs is undoubtedly destroyed in the body. In the case of insoluble prontosil 90 per cent was not recovered, but a large part of this was left behind in the body, staining the tissues an orange color, and excretion was still taking place at the conclusion of the experiment. The discrepancies were greater in infected animals. This may be due to retention by the inflamed tissues or to impairment of kidney function. The infected groups receiving prontosil excreted more sulfanilamide than did the normal groups. In the soluble prontosil experiment equivalent amounts of prontosil and sulfanilamide were excreted, and evidence suggests that half the injected prontosil was reduced. When oral prontosil was also given to patients, a still larger proportion was converted to sulfanilamide. Allowing for the threefold difference in molecular weights, if sulfanilamide is the active agent in prontosil therapy it should be six times as efficient weight for weight as soluble prontosil. This ratio will be affected if there is any great difference in the rates of elimination of sulfanilamide from sulfanilamide-treated and prontosil-treated animals. In the three groups of ten infected mice receiving an average of 25 mg. of soluble

prontosil each, seven, seven and five had died by the fifth day. Six of the ten mice receiving 22.5 mg. of sulfanilamide had died by the fifth day. The experiments thus fail to show any great difference between the two drugs, but for adequate protection of the animals many more than the three injections received would have been necessary. The four control mice had died by the second day. If prontosil has more protective power than is accounted for by the sulfanilamide produced from it, this further action must be other than a simple bactericidal one, for prontosil itself has little or no streptococcus-killing power. It is possible that the therapeutic action of prontosil is due to the sulfanilamide derived from it by reduction in the body.

Overbreathing Tetany.—McCance and Watchorn repeated the work of Barnes and Greaves on overbreathing tetany. They selected two subjects: one who suffered from severe attacks of hysterical overbreathing tetany and a normal woman. Tetany began to develop after a period of only two and one-half to three minutes of overbreathing in the normal subject and after three and one-half minutes in the other patient. The serum calcium rose during overbreathing and fell again immediately afterward. This rise is in agreement with the results reported by a number of authors. The ultrafiltrable calcium also rose during overbreathing. The ratio of the ultrafiltrable to the total calcium remained virtually unchanged in the normal subject. The ratio fell slightly in the patient throughout the whole experiment but was always within normal limits. The cerebrospinal fluid calcium did not fall during overbreathing and did not in fact show any significant change. The inorganic phosphorus of the cerebrospinal fluid also showed no significant change during overbreathing. The results do not confirm those of Barnes and Greaves. The results indicate that the ease with which tetany can be induced by overbreathing has little diagnostic significance. The time at which tetany develops and its severity depend on the susceptibility of the subject to the alkalosis so produced. Thus, tetany may not develop clinically until overbreathing has been in progress for some time, but cases have been recorded in women after very slight hyperventilation. Perfectly normal persons may be as susceptible to alkalosis and tetany as those unfortunate people who are liable to attacks of uncontrollable overbreathing and its sequels.

Cerebrospinal Fluid in Spontaneous Overbreathing Tetany.—In their two cases of overbreathing tetany in which the cerebrospinal fluid and blood calcium contents were estimated, Cumings and Carmichael found that there was no appreciable decrease in the cerebrospinal fluid calcium, although a small decrease took place in the serum calcium.

*Procedure of Professor Enrigue A. Boero and Action of Formaldehyde on Pregnancy. C. A. Masson.—p. 115.

Action of Formaldehyde on Pregnancy.—In 1935 Boero advocated the use of formaldehyde for the interruption of pregnancy. He claimed that this substance causes the death of the fetus but also its retention for some time, making it possible for the patient to continue the treatment of the disease for which the pregnancy was interrupted. Masson made experiments on animals before he attempted to try formaldehyde injections in pregnant women. He chose rabbits and guinea-pigs because these animals have a uterus bicornis, which often allowed him to experiment on either half of the pregnant uterus. Some animals were in their first gestation, some had had many pregnancies and some rabbits were even older than 3 years. To make an intra-amniotic injection of formaldehyde he had to take recourse to a median laparotomy under ether. Then 1 cc. of a 1 per cent solution of formaldehyde was injected into the amniotic sac. In cases of simple pregnancies the fetal movements ceased immediately, often only after a few convulsive movements. In cases of double pregnancy he could observe the phenomenon of continued fetal movements together with uterine contractions. When the quantity of formaldehyde was increased, both fetuses came out dead. Too much formaldehyde caused hemorrhagic lesions in the uterine wall. It was even possible to complete the gestation of the uninjected fetus while the injected fetus remained dead in its amnion. The author's experiences were approximately the same with guinea-pigs as with rabbits and the results obtained led him to attempt the experiment in pregnant women. After emptying the bladder, he inserted a fine needle about two inches above the pubic bone directly into the amniotic cavity. The amniotic fluid flowed drop by drop into the syringe and could be used later for examination. He injected 1.25 cc. of solution of formaldehyde. The patient experienced some pain in the lower part of the abdomen, but this soon subsided. The pain recurred the next day and again after forty-eight hours with some intensity. In the first case the nurse prematurely opened the amniotic sac and about fifteen minutes later the dead fetus was expelled, followed by the placenta. In all the treated cases, pain and swelling of the breasts developed three days later. The quantity of formaldehyde injected may be larger or smaller than 1.25 cc. of the 40 per cent solution, depending on the gravity of the patient's condition. In one case 0.5 cc. of solution of formaldehyde did not kill the fetus but arrested temporarily the patient's toxemia, and expulsion of a live fetus took place sixty-three days later. In another similar case a second injection of 2 cc. of solution of formaldehyde was necessary nine days later, preceded by extraction of 100 cc. of amniotic fluid. Six days later the dead fetus was expelled by normal uterine contractions.

Relapses After Intensive Syphilis Therapy.—Loosli is of the opinion that, since the introduction of arsphenamine, many have become unduly optimistic concerning the treatment of the early stages of syphilis. Repeated reminders not to regard the general rules as applicable to every case are usually disregarded, and the opinion prevails that, if after the completion of the "three course" system the serologic reactions have been negative several times, the case may be regarded as definitely cured. Nevertheless, relapses do occur. The author reports five cases in which, in spite of intensive therapy, sero-

logic relapses became manifest in one case after almost three years and in the other four after about two years. He emphasizes the necessity of a prolonged control and, in some cases, longer periods of treatment than was formerly customary.

Iminazol in Urine in Fatigue.—Massione and Donini made determinations of iminazol in the urine in fatigued persons and found that it is proportional to the intensity of fatigue. According to the authors, fatigue is a reaction of the body to iminazol similar to the body's reaction to histamine. In both cases the body reacts with an increase of the cardiac beats and with blood hypertension, followed by a decrease of the beats and by hypotension; there are increase of glycemia and decrease of the alkali reserve. Fatigue is probably due to the presence of iminazols in the body, which are formed by destruction of muscular proteins during work. The difference in reaction of the body to iminazols in fatigue and to histamine is due to the lesser toxicity of iminazols compared to that of histamine, because the chemical nature of the substances is different, and also to the probable simultaneous production of antagonistic substances to iminazol during muscular work.

Oculocardiac Reflex in Normal Puberty.—Dagnini studied the behavior of the oculocardiac reflex in 230 normal girls ranging in age from 11 to 17 years. He used an apparatus by which the eyes were subjected to constant pressure of 600 Gm. for ten seconds. The production, intensity, time of latency and duration of the reflex were evaluated by the changes in the electrocardiograph, in lead 1, compared to an electrocardiographic curve taken immediately before compressing the eyes. The electrocardiogram was taken with the girls at rest on a bed. Care was taken to show on the tracings the starting and finishing time of ocular compression. The author considers slowing of the heart rhythm, shown by the electrocardiogram, a positive reflex, regardless of its intensity. The reflex was positive in 64 per cent of the cases when it was evaluated by the duration of a cardiac revolution as compared with that of the electrocardiographic curve at rest. It was positive in 44 per cent of the cases when it was evaluated by the number of beats during the ten seconds of ocular compression in comparison with that obtained in the same interval with the girl at rest. The larger number of positive results (75 per cent) was given by girls who, while being at rest, had a pulse frequency of within 70 and 110 beats per minute. The reflex was less frequent in bradycardia and in tachycardia. In 37 per cent of the cases the electrocardiogram showed the presence of respiratory sinus arrhythmia. The oculocardiac reflex was positive in 50 per cent of these cases. In 16 per cent of the cases of respiratory sinus arrhythmia the compression of the eyes made the cardiac rhythm regular. The phase of acceleration that existed in the curve of the patient at rest disappeared during ocular compression. The author's observation gives force to the opinions of those who state that respiratory sinus arrhythmia originates in a disequilibrium of the right vagus and sympathetic nerves. Ocular compression in these cases makes the vagal tonus predominate over the sympathetic with consequent control of the accelerated phase of the cardiac revolution. The most important modification of the electrocardiogram in lead 1 induced by ocular compression in the author's cases was the diminished amplitude

of the P wave, which was observed in 15 per cent of the cases. Changes of the ventricular complex were not observed. The amplitude of the P wave was most diminished in cases of intense oculocardiac reflex. This fact shows that ocular compression has a general action on the rhythm and a special action on the auricle. In a case of intense reflex an autonomic ventricular contraction took place. There were no disturbances of conduction.

Thoracoplasty After Finochietto's Technic.—Albarracín Godoy says that Finochietto's technic for partial superior thoracoplasty with "paradoxical" incision was described in *La prensa médica argentina*, Sept. 18, 1935, page 1779. The technic is as follows: A transverse incision, 15 or 18 cm. in length, is made beginning at the midpoint within the acromion and the spinal border of the scapula (1.5 cm. below the spine of the scapula) and is then directed inward so as to cut the scapular angle. The teguments and then the diaphragmatic dorsal muscles are separated. The large dorsal muscle is dissected downward, whereas the rhomboid and the serratus magnus are dissected upward. Separation of the muscles results in the formation of a tunnel, at the floor of which the interserratic aponeurosis and the small serratus are resected and the musculothoracic space is approached. The scapula is displaced outward. Through the operative tunnel the ribs are resected. The operation ends with reparation of the skin, a drain being left. The author reports satisfactory results in several cases. According to him the operation is ideal for paravertebral and subscapular thoracoplasty. It has the following advantages: Lack of section of the muscles, which results in the production of only slight hemorrhage and trauma and no shock; less intense pain during and after the operation than that induced by the thoracoplasty made by other technics; lack of immediate and late complications. The operation is done under regional anesthesia and can be performed at one time or in several stages, depending on the general condition of the patient. The results of the operation depend on its performance according to indications and early development of the disease.

Restrained Symphysiotomy.—According to Arrieta Yúdice, the technic of Zárate and Ortiz Pérez in "restrained" symphysiotomy is of value for the management of labor in cases of contracted pelvis. The operation, with slight variations, may be described by the following technic: puncture of the skin at the middle of the symphyseal interarticular line and progressive section of the interarticular fibrocartilage and of the arcuate ligament up to the upper border of the symphysis, hemostasis and suture of the opening of the original puncture. The ligaments at the point of insertion of the abdominal muscles are left undisturbed. They form the limit of a pubic diastasis of 4 or 5 cm., which results from the section of the interarticular fibrocartilage and of the arcuate ligament and prevent further opening of the diastasis. The operation is partial and almost subcutaneously performed and permits uneventful delivery of the fetus. Hemorrhages, symphyseal and presymphyseal suppuration, hematoma and incontinence of the urine do not follow the operation, and disturbances of the gait and genital prolapse are not late complications. Owing to the

fact that late pubic consolidation takes place by fibrous proliferation, the amplitude of the pelvis induced by the operation is permanent.

Enterococcic Meningitis.—After pointing out that meningitis of enterococcic origin is comparatively rare, Kemkes reports two cases that were recently observed at his clinic, both of which had a fatal outcome. In the first case the necropsy revealed a purulent meningo-encephalitis, in the second case a purulent leptomeningitis. The bacteriologic examination of the first patient disclosed enterococci in three specimens of cerebrospinal fluid and, during the necropsy, in two pus foci of the brain; in the second patient enterococci were found in one specimen of cerebrospinal fluid and, during necropsy, in a pus focus at the cerebellopontile angle. The strains of enterococci were subjected to various tests and it was found that the enterococci were of the type B in both patients. Since the enterococci were present in pure culture in the spinal fluid as well as in the pus foci, the author thinks that it cannot be doubted that they caused the fatal meningitis.

Calcium Content of Blood in Tetany Resulting from Instability.—Spiegler and Henkel point out that conditions like tetany, osteomalacia, rickets and pregnancy, which are accompanied by disturbances or changes in the potassium-calcium content, are caused by endocrine or similar changes, so that it seems justified to attempt a modification of the calcium metabolism by endocrine therapy. They decided to investigate whether every disturbance in the hormone metabolism is accompanied by changes in the potassium-calcium content. They studied the potassium-calcium content during the intermenstrual and during the menstrual period, employing the electro-ultrafiltration method of Bechold. Tabular reports indicate that in the examined cases the total calcium content was increased; the total potassium content, on the other hand, was reduced. This, of course, is in keeping with the antagonistic character of the two minerals. However, the ultrafiltrable portions of the two minerals showed the same behavior; they increased noticeably during the menstrual period. Entirely different was the behavior of the electro-ultrafiltrable portions of the two minerals; whereas that of calcium was increased during the menstrual period, that of potassium was reduced. The authors further studied the response of the potassium-calcium content to the administration of glandular products during the different menstrual phases. They found that the administration of parathyroid extract produces an increase in the potassium-calcium values during the intermenstrual as well as during the menstrual period. However, the values are not higher than those observed in other cases, so that the total potassium-calcium content of the blood is not more strongly influenced by the parathyroid extract during the menstrual period than is the case outside it. The authors describe two cases of tetany that developed during menstruation and in which no essential changes in the calcium metabolism could be detected. They demonstrate that the calcium metabolism was not changed as it should have been if the tetany was of the thyroprival type and so they designate both cases as pure instability tetanics. They think that the fever, particularly its sudden increase, was

the eliciting factor for the tetany. Another case is cited in which sudden heat stasis produced an attack of tetany outside the menstrual period.

Mumps and Female Genitalia.—Bosch observed that, among the women who came under his observation for sterility, a large number had genital hypoplasia. He thinks that in many of these cases the genital hypoplasia might be the result of the malnutrition during and after the war. However, he also found that the anamnesis frequently revealed an attack of mumps during the prepuberal or puberal age and in many of these cases it was stated that the mumps had been accompanied by pains in the lower part of the abdomen. After directing attention to the concurrence of mumps with orchitis, he points out that some authorities believe that mumps may also cause oophoritis. He himself thinks that the development of mumps during the puberal age and the fact that later genital hypoplasia and sterility are often observed in such patients indicate that disorders of the female genitalia are comparatively frequent after mumps. These disorders probably inhibit further development. Moreover, there is a possibility that other incretory glands, for instance the hypophysis, may become impaired by the mumps. Disorders of the hypophysis could of course result also from the meningitis that is known to occur in mumps. The author says that, as regards fertility, the prospects of endocrine therapy are not favorable.

*Functional Pathology of Diverticulosis of Colon: Question of Late Results of Lead Poisoning. J. Hartmann.—p. 252.

Influenzal Peritonitis.—Uebermuth observed in the course of an influenza epidemic a case of influenzal peritonitis after an initial temporary enteritis. The clinical manifestations were those of an advanced ileus, so that an operation was resorted to. This disclosed a diffuse suppurating peritonitis with subserous focal hemorrhages. These aspects, together with leukopenia, conjunctivitis, initial diarrhea and the development in the course of an influenza epidemic, led to the diagnosis of a genuine peritonitis of influenzal origin. But, although the later course of the case proved that the laparotomy had been unnecessary, the author thinks that under similar conditions reliance on conservative measures is not always justified, because the differential diagnosis is so difficult that, in order to prevent diagnostic errors, laparotomy is advisable whenever there is the least doubt.

Diverticulosis of Colon, Particularly After Lead Poisoning.—Hartmann shows that from the anatomic point of view there is a difference between true diverticula, in which there is a protrusion of the entire intestinal wall, and acquired or false diverticula, in which only the mucosa and submucosa are involved. The first type is usually found on the jejunum and ileum, the second type usually on the colon, especially its sigmoid portion. The author discusses the acquired form, pointing out that old age, obesity and intestinal ptosis are factors predisposing to weakness of the intestinal wall and that peristaltic pressure fluctuations may produce diverticula at sites where the intestinal wall is weak. He devotes himself principally to chronic spastic constipation as cause of the formation of diverticula and particularly their occurrence in lead poisoning. Persons who have had lead poisoning frequently complain in after years of chronic constipation, digestive disturbances and colic. If such patients do not exhibit signs of late sequelae of lead intoxication, a connection of the intestinal disorders with the lead poisoning is usually rejected. However, the author describes two cases which demonstrate that late intestinal symptoms may be the manifestation of diverticulitis and colitis and these in turn probably the result of an earlier lead intoxication. The examination revealed in the first case colitis and diverticulitis and in the second case diverticulosis of the transverse colon. Both patients had a history of lead

poisoning and chronic spastic constipation and the author concludes that it is justified to assume a connection between lead intoxication and constipation on the one hand and the formation of diverticula on the other hand.

Roentgen Treatment of Hyperthyroidism.—Hess reports the results of roentgen therapy in 140 cases of hyperthyroidism. He shows that among the patients who were not influenced or only somewhat improved there were many in whom the treatment had been inadequate. He stresses the necessity of an adequate total dose and of a correct psychologic treatment. There is no mortality as the result of irradiation; on the other hand, there are many severe cases that are unsuitable for other treatments and yield only to irradiation.

Injection of Sugar and Insulin in Roentgen Therapy of Malignant Tumors.—Inouye shows that the efforts to improve the effect of irradiation on tumors tend in two directions; either the ray dosage is changed or the developmental conditions of the tumor are altered. He tried to change the tumor metabolism. He describes experiments on rabbits which proved that the intravenous injection of sugar solution increases the metabolism of the rabbit sarcoma. It was also found that the injection of sugar solution before the irradiation increases the action of roentgen rays on the rabbit sarcoma in that the inhibiting action of the rays is increased. The injection of insulin after the roentgen irradiation supports the inhibiting action of roentgen rays. Thus it is advisable to inject insulin in order to prolong the effect of the roentgen rays. The injection of sugar solution alone improves the general condition of the animals but also the growth of sarcoma. The roentgen irradiation alone reduces the size of the tumors but also impairs the general condition and shortens the life of the animals. The combination of the injection of sugar solution with roentgen irradiations inhibits the tumor growth and prolongs the life of the animals.

Clinical Significance of Nonprotein Nitrogen.—Nonnenbruch defines nonprotein nitrogen as the nitrogenous constituents of the body fluids and tissues that remain after removal of the proteins. The normal quantity of nonprotein nitrogen amounts to about 30 mg. per hundred cubic centimeters. About one half of the nonprotein nitrogen is accounted for by urea and the other half is made up of a number of substances, collectively designated as nonureal rest nitrogen or residual nitrogen, which includes different substances from simple ammonia to complicated products of protein cleavage. He points out that the so-called differential rest nitrogen (D N) has received considerable attention as an indicator of toxic protein decomposition or of the presence of polypeptides. However, his own investigations revealed that the so-called differential rest nitrogen is an entirely unreliable factor. An increase in the residual nitrogen does not signify a renal disturbance, for its constituents are not eliminated as such in the urine but undergo further changes in the intermediate metabolism. An increase in the nonprotein nitrogen does not necessarily indicate renal insufficiency. Increased residual nitrogen values suggest a disturbance in the intermediate metabolism, which is found chiefly in hepatic disturbances that are not always severe. Occasionally increased values are found in syphilitic patients

after treatment with arsphenamine or in hepatic cirrhoses. The highest values are generally observed in cases of acute yellow atrophy. The author reports that, in collaboration with another investigator, he detected a relationship between the residual nitrogen and the urea nitrogen. He cites observations which indicate that urea has an especial significance for the normal and complete course of the intermediate protein decomposition.

Extirpation of Thyroid in Severe Cardiac Defects.—Ewald reviews the results of total thyroidectomy in cases of severe heart disease. Another case is cited in which the thyroidectomy improved the cardiac disorder, but myxedema developed, which could not be adequately influenced by thyroid preparations. The patient became cachectic and died two months later. The author cites several investigators who advise caution in view of the fact that the late results of total thyroidectomy cannot be foreseen; however, he also admits that sudden and considerable improvements have induced others to disregard possible dangers. He himself is of the opinion that as yet total thyroidectomy is not justified when medicinal therapy fails in severe cardiac defects. He thinks that this attitude is permissible until it has been definitely proved that subtotal extirpation of the thyroid is inadequate in such cases.

Roentgen Therapy in Abscess of the Lungs.—Adamowicz and Kulig report their results with the use of roentgen rays in eleven patients who suffered from abscess and necrosis of the lungs. Complete recovery occurred in eight cases; two patients died during treatment, although at first they showed signs of improvement, and one patient relapsed after having been apparently on the road to recovery for ten weeks. It is remarkable that each patient treated with roentgen rays became worse after the first and sometimes after the second application: the patients felt weak and exhausted and their temperature rose, although their cough diminished and became milder, but after the third application a marked improvement could be noticed. The roentgen dosage and the intervals between treatments cannot be schematized but must be regulated according to individual cases.

Treatment of Erysipelas with Prontosil.—Gotlib says that the question of how to treat erysipelas has not yet been solved. In one hospital during the last three years there were more than 700 cases with a mortality rate of 6 per cent. All kinds of medication have been tried, with little success. Lately a dye derivative of sulfanilamide (prontosil) has been tried. Gotlib reports three cases of severe erysipelas successfully treated with this substance. One was a case of inflammation of the tibia of eight years' duration, which was healing slowly but erysipelas developed; the other two were cases of erysipelas of the face. To all patients he administered orally six tablets of this preparation a day. Marked improvement was noted in twenty-four hours and complete recovery occurred in a few days. The amounts used in the three cases were 4.8, 6.2 and 7.2 Gm.

Jacksonian Epilepsy.—On the basis of a study of eighty-two cases of Jacksonian epilepsy in which operation was performed at the Traumatologic Institute of Leningrad, Sozon-Yaroshevich concludes that the primary cause of the condition has not been elucidated. Among the cases studied were motor,

sensory and sensorimotor types. The average time elapsed between the primary disease or trauma and the onset of epileptic convulsions was three and one-half years. The etiologic factors may be of a most varied kind. In their material there were thirteen cases (15.8 per cent) of neoplasm, four (4.8 per cent) of parasites (*Echinococcus*, *cysticercus*), twenty-nine (35.4 per cent) of inflammatory-degenerative type, such as typhus, meningitis and grip; twenty-one cases followed open trauma and fifteen (43.9 per cent) concealed trauma. It is not the primary disease but the pathologic alterations caused by it in the brain and its functions that are responsible for the epileptic seizures. The pathologic changes found were of a chronic type. These were edema and thickening of the pia and the arachnoid, hyperemia and new blood vessel formation, localized serous arachnoiditis with partial localized obliteration of the subarachnoid space, and formation of scar tissue along the course of the blood vessels. These alterations were found in all the cases. On the other hand, alterations in the cortex in the form of scars, softening or thickening with some edema and hyperemia of the pia were found in only half of the cases. Alterations in the dura mater and the bone with ecchymoses, new blood vessel formation and thickening of a diffuse sclerosing type and scars were even less frequent. These pathologic changes are not essential for the production of epilepsy, as they were absent in a number of the cases. The least frequent alterations were those found in the subcortical zone in the form of scars of the white substance or of foreign bodies, such as a bullet, bone or cyst. The most constant were the chronic alterations of the arachnoid and of the cerebral blood vessels. Their localization was most varied. It was found not only in the sensorimotor zone but likewise in the frontal, temporal and occipital localizations. The author concludes that the pathologic alterations in the arachnoid with obliteration of the subarachnoid space and the changes in the cerebral blood vessels with consequent disturbance in the circulation of the cerebrospinal fluid constitute the essential alterations in epilepsy. The scars on the surface of the brain or in its substance are of importance only so far as they are capable of causing alterations in the lymphatic circulation and the distribution of the cerebrospinal fluid in the subarachnoid space of the large hemispheres.

Page's Disease of Nipple. W. L. L. Carol and J. R. Prakken.—p. 771.

Hydrocephalus in Twins and Studies on Heredity. J. A. Stroink.—p. 779.

Encephalitis and Infection.—Heringa reports the case of a youth, aged 16, who, in the course of a septic infection originating in an injury on the left hand, developed a cerebral disorder with the clinical aspects of lethargic encephalitis. Further the author describes three cases of disseminated encephalomyelitis in which the influence of focal infection is evident. He assumes that preexisting neurotropic viruses were activated by the focal infection. Attention is called to the danger involved in dental interventions in neurotropic infections.

Influence of Liver Extract on Melancholia.—Ligterink and his associates point out that Georgi resorted to the injection of adrenal cortex extract in patients with involution melancholia because it is known that this extract reduces the cholesterol content, which is increased in those patients. According to Georgi's report he not only reduced the cholesterol content but also improved the psychotic aspects. The authors point out that these results give rise to several problems, particularly the question whether the improvement in the psychotic disorder is the result of the reduction in the cholesterol content. In trying to answer this question the authors gave injections of liver extract to six patients with involution melancholia. They found that the injections resulted in a reduction of the previously increased cholesterol content of the blood, but they observed no change in the mental condition of the patients. From this observation they conclude that the therapeutic results produced by Georgi cannot be entirely ascribed to the cholesterol reducing action of adrenal cortex extract.

THE DIAGNOSIS OF GASTRIC CARCINOMA AND PEPTIC ULCER

THE COMPARATIVE VALUE OF VARIOUS PROCEDURES,
WITH SPECIAL REFERENCE TO THE
GASTRIC ANALYSIS

CRANSTON HOLMAN, M.D.
NEW YORK

Accuracy in the diagnosis of gastric and duodenal lesions has been greatly increased by improvement made in the technic and interpretation of fluoroscopic and x-ray studies of the gastro-intestinal tract. Nevertheless, the early diagnosis of cancer of the stomach remains a very difficult problem, and it is only through the solution of this problem that the results of treatment can be improved. Up to the present time surgery offers the only satisfactory means of treatment and, as the methods of Billroth and their various modifications are still considered technically adequate, it is doubtful whether in the future any startling advances will be made in the technical approach to curing carcinoma of the stomach. Most of the literature on carcinoma of the stomach concerns itself with variations in the technic rather than with the currently more important subject of early diagnosis. For this reason the experience in this clinic is being summarized to emphasize the importance of a properly performed gastric analysis as an aid in the early diagnosis of gastric and duodenal lesions.

Interest in the examination of gastric secretion has been revived since the introduction of histamine as a gastric secretagogue,¹ but as yet opinion is divided as to the diagnostic importance of the gastric analysis.² It is my purpose in this paper to submit the gastric analyses in 152 proved gastric and duodenal lesions, to point out their importance in the diagnosis of these lesions and to emphasize certain features that are important in obtaining accurate results. I realize that this is a comparatively small group of cases, but it must be remembered that instead of using statistics from the records I investigated and followed each case. With the exception of the cases reported by Bloomfield and his associates, this is one of the largest personally investigated series.

B.: Changes in Gastric Acidity in Peptic Ulcer, Cholecystitis and Other Diseases, *Arch. Int. Med.* **52**: 616 (Oct.) 1933.

The method used in obtaining specimens of gastric juice is that suggested by Bloomfield and Pollard.³ The examination is made after a fast of twelve hours, with histamine used as a stimulus in a dose of 0.1 mg. to each 10 Kg. of body weight. The fasting contents are withdrawn, the histamine is injected subcutaneously, and then the stomach contents are continuously aspirated with a syringe for a period of thirty minutes, the aspirated contents being divided into three ten-minute specimens. The acidity is then titrated against tenth normal sodium hydroxide, Töpfer's reagent and phenolphthalein being used as indicators. The greatest ten-minute volume of secretion and the highest titratable acidity attained are considered the indexes of gastric function.

To insure an accurate determination of this function, three requisites must be recognized. First, the person performing the aspiration must be a physician familiar with the technic of aspirating the stomach, and he must necessarily be interested in the procedure. The delegation of the test to a nurse or to a technician repeatedly leads to error. Second, the stomach must be aspirated absolutely dry before the fractional specimens are collected. This procedure frequently takes from ten to fifteen minutes, and on occasion the test may have to be abandoned for the day because of the constant regurgitation of bile. Third, dilution of the gastric contents must be avoided;⁴ the patient should be required to expectorate all saliva, and all bile-tinged specimens should be discarded. The volume of secretion characteristically follows a more or less regular curve,⁵ and this characteristic can be used to check the accuracy of the procedure. If these three requirements are met, an accurate estimation of the gastric secretion can be made. It has been found that repeated tests on the same patient yield approximately identical results.

The importance of following the described procedure in order to obtain an accurate analysis cannot be stressed too greatly. It has been my experience on numerous occasions that the results obtained by the relatively uninterested technician or nurse will not compare with the results of one who is responsible for and interested in the correct diagnosis of the patient.

I was fortunate in having a small group of patients who had been subjected to the generally accepted analysis by technicians using a modified Ewald test meal. When the results of these studies were compared with those generally reported in the literature⁶ a surprising agreement was apparent in the results. Considering

gastric and duodenal ulcers together, most studies agree that between 10 and 15 per cent are associated with a subnormal acidity or anacidity; in this group tested with the Ewald meal, the percentage was 13. However, when the same patients were subjected to the carefully performed analysis described, the gastric secretion was without exception within or higher than the normal limits.

Since the error in gastric analysis results in too low rather than in too high a value of secretion, my figures for gastric secretion in cases of carcinoma vary little from those usually obtained; i. e., from 10 to 15 per cent of gastric cancer have a normal or high acidity.

The normal standard of gastric secretion as obtained by the method just described has been determined by Bloomfield and Pollard. In general it may be said that the normal range of free hydrochloric acid is between 60 and 110 degrees and the maximum ten-minute secretory volume between 15 and 35 cc. Both the acidity and the volume of secretion tend to become lower with advancing years. It has been found that practically all persons with gastric and duodenal ulcer have high acidity and large secretory volume, but persons with high acidity and large volumes do not all have ulcer.

Differential diagnosis: I. Diagnosis by gastric analysis. II. Diagnosis by operation. III. Diagnosis by x-rays. IV. Diagnosis by history and physical examination.

Gastric analyses were done on ninety patients with peptic ulcer and on sixty-two patients with carcinoma of the stomach in an effort to determine the diagnostic value of a properly performed gastric analysis. The analysis led to a correct diagnosis in 96 per cent of the cases. All the 152 patients either were operated on or came to postmortem examination. All ninety patients with peptic ulcer had a secretion of free hydrochloric acid that fell within normal limits (from 60 to 110 degrees) or were above normal. With five exceptions, the sixty-two patients with cancer of the stomach had a low acidity or anacidity. One of the exceptions (with an acidity of 90 degrees of hydrochloric acid) proved at autopsy to be carcinoma of the duodenum. One other (with an acidity of 60 degrees of free hydrochloric acid) occurred in a man with pyloric obstruction of one year's duration, with an antecedent history of indigestion rather typical of ulcer pain, of ten years' duration. The other three had relatively short histories with no symptoms suggestive of antecedent ulcer.

The accuracy of the gastric analysis compared with other methods of diagnosing ulcer and carcinoma is shown in the accompanying chart. It will be seen that the diagnosis was correct in a larger percentage of cases when it was based on gastric analysis than when any other single method was relied on.

Taking the 152 cases of stomach lesions, both ulcer and carcinoma, as a group, one finds that the clinical diagnosis was correct in 77 per cent of the cases and the roentgenographic diagnosis in 88.2 per cent. It was interesting to find that the diagnosis made by the surgeon at the operating table by inspection and palpation was correct in 93 per cent of the cases, whereas the diagnosis based on the gastric analysis was correct in approximately 97 per cent of the cases.

The following cases may serve as illustrations:

REPORT OF CASES

CASE 1.—A woman, aged 44, had been operated on five months previously for a perforated ulcer. She had had no antecedent symptoms. After operation she was placed on a strict diet, in spite of which she had nausea and a sensation of motion of her stomach following meals. Physical examination was not remarkable except for tenderness in the epigastrium and a well healed right rectus wound.

Roentgen examination revealed a defective duodenal cap with a 25 per cent twenty-four hour gastric retention. The gastric analysis showed a 7 per cent free hydrochloric acid and total acid of 13 degrees.

Exploratory laparotomy was performed. The surgeon diagnosed the lesion as a parapyloric ulcer causing obstruction, and a posterior gastro-enterostomy was done.

The immediate postoperative course was uneventful, but during the next six months the patient gradually lost weight and strength, and a marked ascites developed. At autopsy a primary infiltrating scirrhus carcinoma of the stomach was found, with metastases to regional nodes, omentum and gallbladder.

Clinically, radiologically and at the operating table the lesion appeared to be a benign ulcer; the gastric analysis, however, favored the diagnosis of carcinoma.

CASE 2.—A man, aged 50, had had recurrent attacks of epigastric pain during the preceding three years. For the past two months the pain had become quite severe, was almost constantly present and was associated with nausea and frequent attacks of vomiting. Physical examination was not remarkable save for slight tenderness on deep pressure in the epigastrium. Roentgenograms revealed a large filling defect in the region of the antrum extending as far as the pylorus, suggestive of carcinoma. There was a high degree of acidity in all specimens—the highest was 96, with a secretion of 50 cc.

Gastric exploration was performed and a mass 8 cm. in diameter was found on the posterior wall of the stomach in the prepyloric region. A diagnosis of carcinoma was made and a gastric resection was performed. Serial sections of the lesion failed to reveal any evidence of carcinoma. The patient is now well and healthy, one year after operation.

This is another case in which all methods of diagnosis failed except that based on the gastric analysis.

CASE 3.—A man, aged 50, first seen in February 1934, had had for the preceding four years recurrent epigastric pain relieved by food and sodium bicarbonate. During the six months before entry into the hospital the pain changed to a constant dull ache and caused the patient to lose his appetite. There was no vomiting or melena. The physical examination was not remarkable except for tenderness to deep pressure in the epigastrium. Roentgenograms revealed a penetrating lesion on the lesser curvature, which was diagnosed as a benign gastric ulcer. The gastric analysis failed to show any free acid. The patient was placed on a restricted diet, on which he gained weight and felt greatly improved. He was discharged, to be followed in the outpatient department, where roentgenograms were taken six months later. In spite of symptomatic improvement and a 10 pound (4.5 Kg.) gain in weight, the roentgenograms revealed a slightly enlarged crater. He was readmitted in October 1934, and gastric exploration revealed a huge carcinoma, involving the upper two thirds of the lesser curvature of the stomach, which was deemed inoperable. Anacidity was the only feature in this man's disease that made one suspicious of a malignant condition.

CASE 4.—A man, aged 73, entered the hospital because of abdominal cramps of one month's duration, associated with nausea and vomiting for the past two months. He had lost 15 pounds (6.8 Kg.) in three weeks' time. Examination revealed

that the patient was somewhat undernourished and dehydrated but in no great distress. The abdomen was distended, and moderate tenderness was present in the lower part. No masses were felt. Roentgenograms revealed an almost complete pyloric obstruction and a huge stomach with twenty-four hour gastric retention. The gastric analysis showed 100 degrees of free hydrochloric acid, with volumes of from 40 to 60 cc. for each ten-minute specimen. In March 1933 a gastro-enterostomy was performed under local anesthesia for a complete pyloric obstruction supposedly caused by carcinoma of the pyloric end of the stomach. The postoperative course was uneventful and five weeks later the pyloric end of the stomach was resected in the belief that the lesion was carcinomatous, although it had diminished to half its original size. Serial sections proved that the mass was fibrous tissue surrounding an indurated benign ulcer. Three years after operation he is well and healthy.

These results lead one to some very definite conclusions. Obviously a small percentage of gastric lesions defy all the means now available for their correct diagnosis, including actual exploration, and hence their proper treatment is impossible.⁷ The decision as to whether primarily medical or surgical treatment is to be given any individual lesion should be governed by the patient's age and history, by the roentgenographic appearance and size of the ulcer, and by the gastric secretion. No single finding is infallible, but a lesion in the stomach associated with a low or absent gastric acidity is one that makes operative intervention advisable. This statement can be made only if one presupposes an accurate gastric analysis. Palmer,⁸ in his review of the literature on peptic ulcer and achlorhydria, has shown quite conclusively that a benign ulcer with achlorhydria is very unusual, and in this series there was no benign ulcer with low or absent acid. It is in the small group of patients who have a low acidity with all other examinations pointing to a benign lesion that a properly performed analysis is most valuable. These are the patients on whom a clinician is most likely to delay surgical therapy, and he thereby loses the opportunity to attack the lesion in an early and resectable stage.

CONCLUSIONS

1. Given a lesion of the stomach, a low acidity or anacidity is strong presumptive evidence of carcinoma; such a condition demands surgical intervention. A normal or high acidity in gastric or duodenal lesions points to ulcer.

2. The actual collection of the gastric secretion should be made in the manner described, to avoid inaccuracy.

3. In comparison with the other methods of diagnosis, the gastric analysis, properly done, was the most accurate in the 152 cases studied, although it was not infallible.

4. The information obtained from a properly performed gastric analysis is of practical value in directing one's treatment of a gastric lesion.

He Who Enters His Father's Profession.—To count on the help and influence of other men, to wonder what A and B will do for us, are evidence of weakness. Especially, a young man must be careful to reckon a successful father not among his assets but among his liabilities. For he who enters his father's profession counting on his father's name enters it at his peril: and his venture is the more perilous, if he takes, in the same profession, the same line.—Paget, Stephen: *Confessio Medici*, New York, Macmillan Company, 1931.

FERTILITY AND CONTRACEPTION IN NEW YORK AND CHICAGO

RAYMOND PEARL

BALTIMORE

In connection with an investigation¹ of human fertility and the factors that influence it, based on the complete reproductive histories of 30,949 women delivered in hospitals during 1931 and 1932 and resident in selected large cities east of or on the Mississippi River, it became necessary to extract separately the material for New York City. For comparison with those data the material collected in the second largest city in the country, Chicago, seems particularly suitable. The samples from the two cities are of nearly the same size and in other respects closely similar.

All the original records and histories on which this study is based were obtained from the patients in hospital obstetric services by qualified medical persons (or in a few instances by trained nurses working under medical supervision).

It is my purpose in this paper to present such a comparison. Its interest arises from a number of facts. In the first place these two cities together in 1930 contained 8.4 per cent, or almost exactly a twelfth, of the total population of continental United States. They represent the farthest progression of the process of urbanization in the western hemisphere. All students of population agree that this process has produced as one of its associated phenomena profound alterations, both quantitative and qualitative, in human reproduction. There is also general agreement that one of the basic problems of population today is the critical scientific appraisal of the effects of contraception, as actually practiced. The statements and figures of birth control propagandists cannot quite be relied on to furnish such an appraisal. They tend to confuse the possibilities of their technics as used by selected groups of specially instructed women with the actualities as manifested in random samples of the general population, which include among others ignorant, stupid and feckless folk all too often economically so situated as to make the physiologically adequate practice of contraception by any methods now known extremely difficult if not actually impossible. Birth control practices involve as a considerable element mental attitudes and habituations—in short, individual and group psychologic factors. It is a matter of great interest to know whether there are significant differences in degrees and kinds of controlled fertility in different large communities which are known to differ in their attitudes and outlooks in regard to other matters.

SIZE OF SAMPLES AND AGE OF WOMEN

Table 1 gives the total number of women in the New York and Chicago samples and their average ages in years at the time of record. In this and all following tables in this paper figures in parentheses are percentages, rounded off to whole integers. The separa-

From the Department of Biology, School of Hygiene and Public Health, Johns Hopkins University.

1. This study has been generously aided from its inception by grants from The Milbank Memorial Fund. Detailed progress reports on the work have been published as follows: Pearl, Raymond: *Contraception and Fertility in 2,000 Women*, *Human Biol.* **4**: 363-407 (Sept.) 1932; *Contraception and Fertility in 4,945 Married Women*, *ibid.* **6**: 355-401 (May) 1934; *Third Progress Report on a Study of Family Limitation*, *Milbank Mem. Fund Quarterly* **14**: 258-284, 1936. In these reports will be found details as to the methods of collecting and analyzing the material.

tion into groups of primiparas² (women who have experienced up to the time of record only one pregnancy) and multiparas² (women who have experienced two or more pregnancies) is occasioned by the fact that all earlier studies have shown that the extent and results of contraceptive practices are significantly different in these two groups. "Noncontraceptors" are women who have made no attempt whatever at any time to prevent conception. "Contraceptors," for purposes of present discussion, are all those women who have ever at any time in their reproductive lives made any sort of attempt, however perfect, continuous or adequate on the one hand, or inept, irregular or physiologically stupid on the other hand, to prevent conception from occurring after sexual intercourse.

All the women discussed in this paper were married, had been married only once, and were free of any form of gynecologic disease recognized in the hospitals in

Among the whites, 53 per cent of the New York women were contraceptors (as here defined) as against 64 per cent of the Chicago women. The difference (11 ± 0.8) is probably significant statistically, being nearly fourteen times its probable error. Among the Negroes the corresponding percentages are, as was to be expected, much smaller, being 24 for the New York sample and 47 for the Chicago sample (which however is too small absolutely to be regarded as representative). So far as the whites are concerned, where the samples are large enough to give some confidence in the results the evidence suggests a considerable probability that the attempted practice of birth control is definitely more prevalent in the population of Chicago than in that of New York.³ If a sociological opinion may be ventured, this finding does not seem surprising. On the whole, it is probably a fair generalization that the Middle West is more "advanced" in its attitudes and generally more

which they were delivered. So restricting the material obviously enhances its statistical homogeneity and reliability.

The total material in the two samples comprises 7,530 women, of whom 6,871, or 91 per cent, were whites and 669, or 9 per cent, were Negroes. The white samples are almost identical in size in the two cities, but the Negroes are much better represented in the New York than in the Chicago sample. In the New York sample 35.8 per cent of the white women were primiparas, and in the Chicago sample 43.4 per cent. Both these figures represent an excess over the conditions in the United States as a whole. In the United States registration area in 1930 (which included all the states with the exception of South Dakota and Texas) 32.24 per cent of the white women bearing children were primiparas.

The excess of primiparity in the present samples is probably explained chiefly by the fact that these women were all delivered in hospitals. The Negroes in the present samples show smaller percentages of primiparity than the whites, as would be expected a priori.

2. These terms are used because of their common employment, rather than the more precise designations primigravidas and multigravidas, for the categories defined in the brackets. Since the definitions of the categories make the meaning perfectly clear, probably only the pedantic purist, if any one, will be annoyed by the terminology used.

open minded toward relatively new ideas and more receptive to propaganda than the Atlantic seaboard. If this is generally so there is no reason why the attitude toward birth control should be an exception.

In average age the women of the Chicago sample tend on the whole to be a little older than those of the New York sample, but not by amounts great enough to be very significant reproductively. The age differences probably chiefly reflect a little greater postponement of marriage on the average in Chicago than in New York, together with a little lower fertility rate, as will presently appear (the ages in table 1 being average ages at the time of record; i. e., the time of birth of each woman's most recent child).

EXPOSURE TO RISK OF PREGNANCY

In reaching a critically adequate measure of fertility it is necessary to introduce the actuarial concept of exposure to risk of becoming pregnant. In earlier work⁴ the mathematical development and treatment of this concept have been fully discussed. Here it must suffice to say that, as a woman is not exposed to risk

3. It may be stated at this point, although space is lacking to present the detailed evidence in proof, that the New York and Chicago samples of white women are closely similar in respect of social, economic, educational and racial composition.

4. Pearl, Raymond: Factors in Human Fertility and Their Statistical Evaluation, *Lancet* 2: 607-611 (Sept. 9) 1933.

of becoming pregnant when she is already pregnant or in the puerperal state, the figures given in table 2 state essentially the aggregate time in years spent during their married lives by the women in the samples while they were not pregnant or in the puerperium. Table 2 gives the aggregate exposure to risk of the two samples, in person-years, and the average number of years of exposure per woman.

The total exposure to the risk of becoming pregnant of these 7,540 women was 22,874.3 person-years, or an average for the whole lot of three years and eleven days per woman. The multiparas account for the bulk of the exposure. Thus in the New York sample while the white multiparas constituted only 64 per cent of the white women they accounted for 90 per cent of the total exposure. In the Chicago sample of whites 56 per cent of the women were multiparas, but they accounted for 83 per cent of the total exposure to risk of pregnancy. The Negroes show a similar relationship. It depends basically on a fact more clearly seen from the average figures of item 3. Primiparas as a class become preg-

indicated by taking the ratios of the contraceptive to the noncontraceptor means. So doing shows that the delay from marriage to first conception was 2.8 times greater in New York white contraceptors than in noncontraceptors, 2.3 times greater for New York Negroes, 1.9 times greater for Chicago whites, and 2.8 times greater for Chicago Negroes. So far as this criterion may be taken as indicative, the suggestion is that the Chicago white women in the initial portion of their married lives practiced contraception less effectively on the average than did the New York women of corresponding status, although as was shown in table 1 a great many more proportionally of the Chicago than the New York newlyweds tried it.

The average exposures to risk of the multiparas (table 2, items 4c and d) state the number of years of married life spent outside the pregnant and puerperal states. These averages are higher, class for class, in the contraceptive groups than in the noncontraceptor groups, as would be expected if the attempts at birth controlling had any practical effect at all. The relative effective-

* Meaning that in this class of women contraception was not effective at all in lowering either pregnancy or live birth rates, since these rates were higher, by the stated percentages, in contraceptors than in noncontraceptors.

nant with much less prolonged exposure to risk than do multiparas.

In the case of the primiparas the figures under item 4 give the average lengths of time in years, for the several groups, between marriage and first conception (beginning of first pregnancy). Thus, to take New York white primiparas noncontraceptors as an example, the figure 0.51 means that on the average these women spent only a little over six months after marriage before they were pregnant. The Chicago women in the same category exhibit an average delay between marriage and first pregnancy over three months longer (9.72 months exactly). This is the first indication of the generally slightly lower apparent innate fertility exhibited by the Chicago as compared with the New York samples, both white and Negro. As we proceed, more evidence supporting this inference will appear.

From item 4 there also appears the first indication as to the effectiveness of contraception. If the primiparas contraceptors averages of item 4b are compared with those of primiparas noncontraceptors (item 4a) it is evident that the practice of contraception has substantially increased the time interval between marriage and first conception, as it was intended and would be expected to do. This is true for all groups, white and Negro, New York and Chicago. The relative effectiveness of the contraception, as practiced, may be simply

ness can be simply indicated by the same device that was used for the primiparas. So doing, it appears that the New York multiparas contraceptors enjoyed 1.4 times as many years of married life free from pregnancy as did the noncontraceptors; for the New York Negroes the figure is 1.1 times, for the Chicago whites 1.2 times, and for the Chicago Negroes 1.1 times. These figures confirm, so far as they go, two well established points: that contraception is less effectively practiced by multiparas than by primiparas, and by Negroes than by whites. Comparing the New York and Chicago white samples, the suggestion again is that the attempts of Chicago multiparas at contraception were less effective than those of the New York multiparas, though proportionally more of the Chicagoans tried it.

FERTILITY AND CONTRACEPTION

In table 3 are given the number of pregnancies experienced and live births produced per hundred years of exposure to risk of pregnancy in the several classes, and also the percentage effectiveness of contraception, as practiced, in lowering the pregnancy and live birth rates.

At this point it will be well to state categorically that here and elsewhere in this paper the discussion has to do with the effectiveness of the total contraceptive efforts of defined groups of persons in the sense only of lowering pregnancy or birth rates, or prolonging the

portion of married life spent free of pregnancy, when these groups are compared with similar groups in which there was no contraceptive effort whatever. The data here discussed have no bearing whatever on the question of whether birth control gadget A is better or worse than gadget B, or the degree to which either is biologically effective in reality. The discussion concerns only the comparative reproductive performance of defined groups of women, of which groups some have attempted to alter the expression of fertility by resort to contraceptive technics, whereas the other groups have made no such attempt.

In beginning the discussion of table 3 it will be well first to explain an apparent paradox in the figures. To one not accustomed to handling this sort of material and not familiar with the mathematical treatment to which it has been subjected, it may seem odd at first glance to see that 195.4 pregnancies and especially 188.6 live births resulted from each hundred years of exposure to risk of pregnancies among New York white primiparas noncontraceptors, to take them as an example. This however is physiologically all right, odd as it seems. It merely means that the time between marriage and conception was under six months in well over half the cases. If it had been exactly six months

percentage lowering in contraceptive as compared with noncontraceptor classes is less in the Chicago sample than in the New York sample by 17.0 ± 1.3 per cent for primiparas and by 10.9 ± 1.0 per cent for multiparas. Among the multiparas the Negroes evidently practice their contraception much less effectively than the whites, but among the primiparas the racial differences are not so marked.

REPRODUCTIVE WASTAGE

Pregnancies that terminate in miscarriages, abortions or stillbirths—in short, in any other way than by live births—represent reproductive wastage. The organism has been put to physiologic trouble to no useful end. The extent of this wastage quantitatively is shown in table 4. In this table the reproductive wastage rates per hundred pregnancies experienced as given in item 10 are obtained by subtracting each figure of item 9 from 100.

Among the white women the reproductive wastage rates are somewhat lower in the Chicago than in the New York sample. So far as concerns the total group they are significantly lower. This is possibly connected with the greater prevalence of contraceptive efforts among Chicago women. Reproductive wastage rates in

TABLE 4.—Reproductive Wastage

d. Among multiparas contraceptors.....	16.0	14.4	13.2	18.8
	14.2	13.5	13.4	16.4

in all the cases, the figure 195.4 would have been exactly 200. A similar situation, *mutatis mutandis*, exists in all other cases in which the rates in the table are greater than 100. The intervals (in years) of freedom from pregnancy (and the puerperal state) were in each case numerically less than the pregnancies or live births experienced.

From table 3 the following inferences seem reasonable: First, the white women of the Chicago sample, in whatever class, exhibited lower fertility rates than the corresponding New York women whether measured by pregnancies or live births or whether with or without contraception. The difference between the New York and Chicago samples as wholes in respect of pregnancy rates (13.9 ± 0.7) may be regarded as very probably significant statistically, being almost twenty times its probable error. In the second place it appears that in the New York sample the Negroes, in each class except the multiparas contraceptors, exhibit somewhat lower fertility rates than the whites, while the opposite appears to be true in the Chicago sample. But, as has already been pointed out, the Chicago Negro sample is too small to give results of any firm reliability. Furthermore, it is doubtful that the New York white-Negro differences would be confirmed in larger samples.

Turning now to items 7 and 8, the suggestion again is that the Chicago white women were less effective contraceptors than the New York white women, class for class. The differences in the percentages measuring effectiveness of contraception (items 7 and 8) are statistically significant to a high degree of probability. Thus considering the live birth rates (item 8) the per-

both cities are much higher in multiparas than in primiparas. This result accords with all experience regarding the subject. The wastage rate rises with parity.

Although the samples are not large enough to be completely probative, the figures bring out an interesting point to which attention has not hitherto been called. There is an apparent tendency, with the Chicago white multiparas forming the only exception, for the reproductive wastage rates to be lower among the contraceptors than among the corresponding classes of noncontraceptors. The entire material at our disposal will be analyzed relative to this point as soon as possible, because it is a matter of considerable interest especially in relation to the controversy that has gone on for years as to whether birth control is physiologically harmful to the female reproductive mechanisms.

INDUCED ABORTIONS

The reproductive wastage figures of table 4 indicate the totals of all such wastage. Because of the fact that deliberately induced abortion is resorted to by many a harassed female as an adjunct to, or surrogate for, contraceptive efforts, it is desirable to examine separately the rates for abortions admittedly induced by the woman herself or by some other person acting criminally with her consent to relieve her of her difficulty. It is to be understood that abortions ethically induced for therapeutic reasons by reputable physicians are not included in the figures of table 5. They include only wilful termination of unwanted pregnancies.

The implications of table 5 are thought provoking. The 1,328 New York white multiparas contraceptors

admit that one in every twenty-four pregnancies they have experienced in their aggregate reproductive lives has been terminated by a successful criminal abortion; furthermore, on their own admission, roughly one in every eight of them has had at least one induced abortion; and finally they admit that approximately 30 per cent of the aggregate reproductive wastage they have experienced has been due solely to criminal abortions induced by themselves or by somebody else. It is probable that the admitted figures are short of the whole truth, though by how much it is impossible to say. Current statements in popular lay journals about the frequency of criminal abortion in the general population considerably exaggerate any conclusion that can be supported by critical scientific evidence. It is true, as indeed our unpublished records show, that a great many women attempt to induce abortions but fail. A careful critical study of individual records leads me to the opinion that the figures of table 5 are not greatly below the unknown reality, and certainly not as much below as some would have us believe.

While the New York multiparas contraceptors have been discussed first as an example, the picture presented

3. At the same time contributing substantially through the direct and indirect taxes they, as families, pay to the support of an intensive and statistically highly successful public health program of keeping babies alive and in good health.

Such a picture tallies badly with our national pride in being a socially enlightened, intelligent and progressive people.

Perhaps the most interesting thing that table 5 shows—a point that so far as I am aware has not hitherto been supported by numerical evidence as distinguished from a priori opinion—is that resort to wilfully induced abortion is much more common among women who practice birth control than it is among women who do not, so far as may be judged by the evidence afforded by these two samples. There is reason to believe, and it is expected that later in another place it will be demonstrated, that New York and Chicago are in no wise peculiar in this respect but that our total material will show the same thing. The result is one to be expected on the lower levels of behavioristic psychology. The abortionist is called on to rectify the inadequacies of birth control.

d. Among multiparas contraceptors.....	13.9	9.3	7.8	0

by table 5 as a whole is not exactly a pleasant one from any point of view. Remember that the table contains only women living in wedlock who have been married only once, and are free of gynecologic disease—in other words, generally not people of loose morals. These are records of families, living together and rearing children, on the whole representative of the most substantial sort of the traditionally typical American family at each social and economic level represented in the data, from “very poor” through “well-to-do and rich.” The figures as to purposefully induced abortion are not estimates or wild exaggerations based on emotional opinions. On the contrary they are records of actual happenings, which admittedly probably somewhat understate the complete facts but can therefore be accepted with greater confidence as establishing minimal values, below which the truth cannot lie.

What emerges is that, in our two largest cities, samples of white child-bearing women that are known to be fairly representative of the population (cf. evidence in Third Progress Report cited earlier) from which they come are exhibiting the following kind of behavior:

1. Deliberately causing from one sixth to more than one fifth of their aggregate reproductive wastage.

2. By so doing voluntarily taking one of the most serious risks to their very lives as well as to their future health and well being that a woman can take short of suicide or major self mutilation.

So far as the present sample may be taken as indicative, the suggestion is that the Chicago white women resort somewhat less to induced abortion than the New York women. Larger samples would be necessary to be quite sure about this, but the suggested trend is probably real. The induced abortion rate tends to be lower among the Negroes than among the whites, as is clearly shown by the New York figures.

SUMMARY

Certain aspects of the reproductive histories of 3,951 women dwelling in New York City and 3,589 dwelling in Chicago were analyzed and compared. All the women in both samples were living in wedlock, had been married only once, and were free of any recognized form of gynecologic disease. The age distribution of the women was substantially similar in the two samples, with somewhat greater average ages in the various subgroups of the Chicago sample, but not sufficiently so to affect any result.

1. The white women of the Chicago sample appear to be somewhat less fertile on the average as a group than the white women of the New York sample, whether measured by pregnancies experienced or live births produced.

2. Attempted contraception was more frequent among the Chicago than among the New York white women, the percentage of contraceptors being 64 in the former city and 53 in the latter.

pen, hurries to the window and pulls the window shade, utters some comment, then mounts the scale and is off again.

Once this inhibiting function is acquired, it may be diminished or destroyed by certain major damage to the brain. The outstanding disease process that affects this function is encephalitis. It is well known⁴ that children who have suffered from lethargic encephalitis present behavior disorders, often characterized by distractibility and hyperkinesis. Recently a similar clinical picture has been drawn for children who have sustained severe cranial trauma. Blau⁵ reported cases of children who have suffered cranial trauma who developed this same restless, purposeless hyperactivity.

The behavior of our patient is quite similar to the manifestation of certain retarded individuals and of those who have suffered encephalitis or brain trauma. At first meeting he appears vivacious, lively and talkative. When studied critically, one is impressed by his hypermotility, by his rapid change from one subject to another. At times the rapid change from subject to subject matter in his speech resembles the flight of ideas so common among manic patients. His hyperkinetic tendency shows itself in his leaping to the bed and then off to gaze through the window, back to finger the doctor's tie, and so forth.

The behavior difficulty at home arises from the clash between the uncontrollable hyperkinetic tendency and the unsuccessful efforts of teachers and parents to regulate it. When Clarence was commanded by his teacher to study for an hour and gave his "promise" to do so, he was able to maintain interest only for several minutes. Then he began to inspect the cover of the book, open and close the desk, gaze at the clothes of the other pupils, the way their hair was combed; then his gaze would be directed to the windows, the sky, the song of the birds. At the end of the hour he knew very little of the contents of the chapter he was supposed to read. The teacher upbraided him and the next day he did not appear at school. At home there was similar friction. He was given duties which he failed to perform. When reprimanded he would reply by lying, cursing and fighting. The patient can be well understood in the light of Bond and Appel's report⁴ that such hyperkinetic children do better when removed from the usual restraint of parents and teachers. Obviously the attempt to curb the irresistible impulses would prove unsuccessful.

One may wonder why a hyperkinetic disorder occurs in youth and not in adults. With traumatic damage in older persons we have frequently seen depressed states or paranoid reactions. It seems as though in youth and childhood interest and attention are often directed outward. This "extroverted" tendency arises out of a child's eagerness to learn. Such curiosity may not be primary; it may be aroused by the novelty, the strangeness, the unusualness of every situation. A like curiosity appears in an adult traveling for the first time amid new surroundings. For example, we recently drove in New York City with a companion who was there for the first time. His reaction to the environment was similar to that of Clarence's continuous hyperkinetic distractibility. He looked downward to

hear the roar of the subway, up at the elevated trains. He strained his neck to see the tall buildings. He was surprised at the large crowds on Fifth Avenue. He made comments and exclamations. The other members of the party, who had been in New York on several occasions, looked about, half bored, and more concerned with the visceral feelings of hunger.

As a youngster and adult are walking along the street, apparently looking at the same scenery, there may be a fundamental difference in the pathway of the major mental interest. The child looks out intently, notes keenly, observing and recording in his memory, reacting with exclamations and numerous questions. The adult (if not on a scientific journey of observation) likewise looks out, but as he notes these familiar surroundings his mind wanders inwardly to memories which are recalled and to internal problems and complications. Though looking outward at what might be glorious scenery, he may heave a deep sigh because of an internal sadness or may chuckle because he recalls a witticism he heard the night before.

When the cortex has been damaged by a virus, mechanical or vascular change, the impairment affects the most difficult function. In the youngster this consists of reducing distractibility and increasing concentration. A loss in cortical function reduces this progress and accentuates the distractibility. In older individuals, a similar loss of cortical control might reduce the ability to look outward, to study reality. Thoughts are more quickly introverted; the outer environment is less readily understood. In the face of physical difficulties and a misunderstood environment there is a tendency toward worry and suspicion, all of which leads to a depressed or paranoid reaction.

Blau⁵ postulates the theory that this hyperkinetic syndrome might be due to frontal lobe damage. This is a possibility in our case because there are no localizing signs.

Aside from the organic brain change, one must consider the influence of several other factors: the scars in the scalp and the defect in the skull bone, together with the fear of possible further brain damage. We do not consider this an important factor, because Clarence does not manifest anxiety or depression. One must consider also the possible effect of the scarred and deformed hand and various scars on the body. Clarence, however, minimizes these difficulties. His story does not consist of a shyness or backwardness produced by these deformities. The major disorder is therefore to be interpreted in the light of the cortical brain change and not in that of the surface scars and deformities.

It appears as though a similar behavior disorder may result from brain trauma, whether it is produced by electricity, direct mechanical violence or infection. The age of the patient is the more important factor in the type of the manifestation.

CONCLUSION

An apparently well adjusted, normal youngster, after he sustained a serious brain damage from electricity, developed a profound behavior disorder, characterized largely by hyperkinetic tendencies. Apparently a like picture may result from a brain lesion in youth, whether the lesion arises from virus, mechanical or electrical injury.

EXCESSIVELY RAPID HEART RATES

REPORT OF A CASE WITH AUTOPSY

JAMES ALEXANDER LYON, M.D.

WASHINGTON, D. C.

The ventricles of the human heart have rarely been observed to pulsate at a rate approaching 300 per minute. Only sixteen cases in which there was a ventricular rate of 280 or over were found in the literature (table 1). In ten of these the rate was confirmed by graphic tracing; in the remaining six the count was by stethoscope only. A ventricular rate of 300 beats per minute was recorded electrocardiographically in four cases. In no case was an electrocardiogram published showing a rate that exceeded 300 per minute. Werley¹ published a polygram presenting a ventricular rate of 307. Blackford and Willis² stated that a patient having auricular flutter with a two-to-one block entered their office during a paroxysm of one-to-one response which lasted nearly two hours. A heart rate of 320 was counted by means of the stethoscope. Later during the attack an electrocardiogram was taken which showed a rate of 300 beats per minute. Duken³ reported that in the case of an infant whose heart rate was 300 by stethoscopic count an electrocardiogram showed a rate of what appeared to be 320 beats per minute but that the tracing was not distinct enough to differentiate the complexes definitely. He did not publish the electrocardiogram. These three are the only reported rates above 300.

It seems probable from this review that the upper limit at which the ventricles of the human heart can maintain their rate of pulsation is approximately 300 per minute. Lewis and his associates⁴ found that when in animal experiments the auricles of the mammalian heart were stimulated to rates surpassing 300 per minute the ventricles beat at a slower rate. The auriculo-ventricular node, because of the greater length of its refractory period, failed to transmit each stimulus to the ventricles and dropped beats or two-to-one rhythm occurred. Two-to-one response to stimuli appeared in the auricular muscle at rates of approximately 450 per minute, in the auriculoventricular node at rates approaching 300 per minute, and in the ventricular muscle at an intermediate rate.

In the following case a ventricular rate of from 310 to 313 beats per minute was recorded electrocardiographically. This rapid rate occurred during an attack of streptococcal meningitis in an infant 4½ weeks of age. When the patient came to autopsy three weeks later the heart was found to be grossly normal. A microscopic examination of tissue showed no evidences of infection or fibrosis of the heart muscle. The electrocardiogram, in addition to presenting a rate faster than any so far recorded in the literature, presents an interesting problem of interpretation (fig. 1).

REPORT OF CASE

A colored female child, born Jan. 16, 1934, was admitted to the Children's Hospital February 15, thirty-one days after birth,

Dr. P. A. McLendon of Washington furnished the opportunity of observing this case. Dr. E. C. Rice made the postmortem report. Dr. R. M. Choiser made the microscopic study of tissue and Dr. Paul D. White contributed valuable suggestions to the reporting of the case.

because of difficulty in breathing, rapid heart action and attacks of vomiting. The infant had been normal at birth and had weighed 7 pounds 8 ounces (3.4 Kg.). The mother's health was good and she had a normal pregnancy and delivery. The infant was breast fed and at the time of her admission weighed 9 pounds 2 ounces (4.1 Kg.). The mother stated that the child had apparently been well until 3 o'clock the morning of the 15th, when she noticed that it was breathing with difficulty. This condition remain unchanged. Beginning at 6 o'clock the child had several attacks of vomiting and later on during the morning it passed a small amount of blood by rectum.

On admission the temperature was 99 F. and the respirations were 40 per minute and irregular. The heart rate was too rapid to count accurately, but it was estimated to be over 300 beats per minute. The heart was not enlarged. A faint systolic murmur was heard intermittently in the mitral area. The lungs were clear. The abdomen was distended. The liver and spleen were not palpable.

On February 17 the hemoglobin was 55 per cent, the red cell count 3,200,000 and the white cell count 9,500, of which 37 per cent were lymphocytes and 63 per cent polymorphonuclears. An examination of the urine was essentially negative. February 19, the fourth day following the onset of the rapid rate, an electrocardiogram demonstrated an auriculoventricular rate of 310 beats per minute in leads 1 and 2 and 313 per minute in lead 3 (fig. 1). A teleroentgenogram taken February 23 showed slight enlargement of the heart (fig. 2). A diagnosis of paroxysmal tachycardia was made by one of the house physicians.

On the day following admission the ventricular rate varied between 150 and 300 beats per minute. During the subsequent ten days the heart was occasionally observed to be beating at approximately 300 beats per minute, although it more often ranged between 130 and 180, with the radial and temporal pulses coinciding. During the remaining ten days of the infant's life the heart rate ranged from 130 to 180. An electrocardiogram taken March 2 demonstrated an auriculoventricular rate of 130 beats. Otherwise the electrocardiogram was normal (fig. 3).

The patient continued to have an elevated, fluctuating temperature ranging from 99 to 105.2 F. She steadily lost weight. February 27 the hemoglobin was 72 per cent, the red cell count 4,300,000 and the white cell count 16,800, of which 27 per cent were lymphocytes and 73 per cent polymorphonuclears. March 3 a catheterized specimen of urine showed a few white blood cells, occasional red blood cells and a few hyaline casts. March 6, considerable swelling developed over the left upper part of the chest and about the base of the neck on the left side extending out to the point of the shoulder. A roentgenogram taken on the same date demonstrated a fusiform swelling in the middle third of the left clavicle, the upper border of which was slightly irregular. The blood count at this time showed the hemoglobin to be 57 per cent, the red cell count 3,000,000 and the white cell count 25,000, of which 14 per cent were lymphocytes and 85 per cent were polymorphonuclears. On the following day the patient developed erysipelas involving the left side of the neck and the left shoulder. March 8, the twenty-first day after admission to the hospital, the patient died.

At autopsy the meninges were found to be injected and to show a grayish exudate, which covered the surface of the brain. The heart was normal in size and appearance. The musculature was firm. The foramen ovale and ductus arteriosus were closed. The right pleural cavity contained about 15 cc. of yellow blood-tinged fluid. The right lung was of a deep grayish purple, with evidence of atelectasis. In the lower lobe an irregular reddish gray area, approximately 2 cm. in diameter, extended internally about 1 cm. and had the appearance of an infarct. On section this area was found to be superficial and not consolidated. The left lung was moderately congested. The liver was enlarged 3 cm. below the costal margin in the right midclavicular line. On section it was grayer than usual, possibly because of toxemia. The kidneys, spleen and adrenals showed evidences of passive congestion. Microscopic examination of tissue showed that in the meninges the pia-arachnoid was thickened and that there was an infiltration of leukocytes, round cells predominating, with some polymorphonuclears. Some disintegrating material was also present. The underlying substance was edematous. The muscle fibers of the heart appeared to be separated more than usual, possibly because of edema. No evidence of inflammatory reaction was

noted. The alveoli of the lungs contained a large amount of albuminous fluid. Atelectasis was marked in some sections. In the tissues of the liver there were evidences of chronic passive congestion with collections of leukocytes and proliferation and infiltration of connective tissue cells. The appearance of many of the hepatic cells was suggestive of toxic degeneration. The follicles of the spleen were much compressed by an increased amount of red blood cells. The reticulum was prominent. Collections of brownish pigment were found throughout

nerve fibers or of nerve cells in any portion of this section. In some areas there was a very mild fragmentation of the muscle fibers. The papillary muscle was well developed. A section through the heart at the upper portion of the septum close to the atrioventricular junction revealed several groups of sympathetic nerve cells located beneath the endocardium. These cells were large, being six times the diameter of a red blood cell, and they had a faintly basophilic cytoplasm and two or three protoplasmic processes extending from each cell body.

TABLE 1.—Summary of Reported Cases of Excessively Rapid Heart Rates

Number	Author and Date	Sex, Color, Age	Associated Diseases	Arrhythmia	Attacks, Duration and Number	Ventricular Rate	Graphic Tracing	Symptoms Produced by Rapid Heart Action	Outcome	Necropsy
1	Mackenzie, 1911, 1915	♂ W 47 yrs.	Mild typhoid prior to onset	Auricular flutter with 1 to 1 response	30 to 60 minutes, several attacks	290-300	Phelebogram	Prostration and weakness	Resumption of normal rate	
2	Lewis, 1915	? W 3 mos.	Not stated	Auricular flutter with 1 to 1 response	"Several hours"	270-290	Electrocardiogram	None present	Not stated	
3	Koplik, 1917	♂ W 22 mos.	"Grip" prior to onset	Paroxysmal auricular tachycardia	"A few days," several shorter attacks	224-288	None at 250 or over	Cyanosis, dyspnea, passive congestion during first attack	Resumption of normal rate	
4	Blackford and Willis, 1918	♀ W 32 yrs.	Exophthalmic goiter	Auricular flutter with 1 to 1 response	"Nearly 2 hours," many attacks	300	Electrocardiogram	None present	Resumption of normal rate following thyroidectomy	
5	O'Flynn, 1925	♀ W 8 mos.	Diagnosis undetermined; "intestinal irritation"	Paroxysmal auricular tachycardia	8 days, 2d attack lasting 24 hours	200-300	None	At times cyanosis, passive congestion	Resumption of normal rate	
6	Werley, 1925	♂ W 4 days	Diagnosis undetermined	Paroxysmal auricular tachycardia	Several hours, 2 attacks	300-307	Polygram	Cyanosis	Death, 3d day after onset	Widely patent foramen ovale, congestion of cardiac vessels
7	Sachs, 1926	♂ W 3 yrs.	Heart disease	Paroxysmal auricular tachycardia	Several hours, 3 attacks	280	Electrocardiogram	Cyanosis and dyspnea	Death 1 year after onset	Myocarditis, dilatation, hypertrophy
8	Colgate and McCulloch, 1929	♂ C 3½ wks.	None present	Paroxysmal auricular tachycardia	2 hours or more	291	Electrocardiogram	Dyspnea, enlargement of liver	Resumption of normal rate	
9	Russell and Ellison, 1927	♀ W 15 mos.	"Congenital heart disease"	Paroxysmal auricular tachycardia	5 days, 2d attack 3 days, rate 240	290-300	Polygram	At times cyanosis and restlessness	Resumption of normal rate	
10	Herapath, 1928	♂ W 17 yrs.	Influenza prior to onset	Auricular flutter with 1 to 1 response	Many brief attacks following exertion	288	None	Dyspnea	Resumption of normal rate	
11	Langley, 1928	♂ W 14 yrs.	None present	Paroxysmal auricular tachycardia	A few brief attacks	300	Electrocardiogram	None present	Resumption of normal rate	
12	de Bruin, 1930	♂ W 5 wks.	"Probable encephalitis"	Paroxysmal auricular tachycardia	Duration not stated, several attacks	250-250	None	Cyanosis, dyspnea, passive congestion	Resumption of normal rate	
13	Duken, 1933	♀ W 8 wks.	Diagnosis undetermined, "bloody vomitus and stools"	Paroxysmal auricular tachycardia	3 days, 2 shorter attacks	200-300	None	Cyanosis, passive congestion, one attack of syncope	Resumption of normal rate	
14	Bunn, 1933	♂ W 50 yrs.	Exophthalmic goiter	Paroxysmal ventricular tachycardia	5 hours, single attack	300	Electrocardiogram	Collapse, weak pulse, pulmonary edema	Resumption of normal rate	
15	Farr and Wegman, 1935	♂ W 3½ wks.	None present	Paroxysmal auricular tachycardia	10 hours, 6 attacks over 8½ months	300	Electrocardiogram	Cyanosis, dyspnea, passive congestion	Resumption of normal rate	
16	Clarke, 1935	♂ W 1 wk.	None present	Paroxysmal auricular tachycardia	51 hours, several attacks for 5 days	300	None	Cyanosis, dyspnea, passive congestion	Resumption of normal rate	
17	Lyon, 1937	♀ C 4½ wks.	Streptococcal meningitis	Auricular flutter with 1 to 1 response	Additional Case 10 hours, several attacks for 10 days	310-313	Electrocardiogram	Dyspnea	Death, 3 weeks after onset	Heart, normal

the sections of the spleen. The tubular epithelium of the kidneys was poorly staining and much swollen, representing evidence of the toxic effect on the organ. An anatomic diagnosis was made of (1) purulent meningitis, (2) empyema, right, (3) bronchopneumonia and atelectasis, (4) subacute hepatitis and (5) erysipelas.

A microscopic study of tissue taken from the interventricular septum showed cardiac muscle fibers which were small, thin and closely approximated to one another, with round nuclei which took a pale basophilic stain. The endocardium was smooth, unbroken, and lined by an endothelium and a basement membrane of areolar connective tissue. The capillaries in this tissue were abundant, moderately dilated, and congested with red cells of the nonnucleated variety. There were no evidences of

The cytoplasm was clear. Under high power, numerous small granules were visible. The nucleus was markedly hyperchromatic and of an even texture throughout. None of its finer markings could be made out. A few small nerve bundles could be traced for a short distance down beneath the endocardium. A section through the right auricle and ventricle, taken in the longitudinal axis on the anterior surface, revealed moderate fragmentation and segmentation of the muscle fibers and considerable dilatation and congestion of the capillaries. The nuclei of the muscle fibers in this section were larger and slightly paler staining than were those in the sections taken from the septum. There was no evidence of nerve tissue in this particular section. A section taken through the right auricle just beneath and to the left of the inferior vena caval

orifice revealed three small sympathetic ganglions immediately beneath the endocardium. The cells in two of these ganglions were about six times the diameter of a red blood cell and they had a slightly basophilic cytoplasm with a round, mildly hyperchromatic nucleus. Two or three small dendritic processes extended from each cell body. In the third ganglion the cells were fainter, paler staining and appeared to have undergone some mild change. The vessels in this section were mildly congested. The heart muscle fibers were fairly well developed. There was no fibrosis seen in any section.

SUMMARY

A colored female infant, 4½ weeks of age, had an attack of rapid heart action lasting more than ten hours, during which time the ventricular rate was approximately 300 beats per minute. Similar attacks of shorter duration occurred during the first ten days that the child was under observation. During the intervals between attacks the heart rate varied from 130 to 180. On the fourth day following the onset of the rapid rate an electrocardiogram showed a ventricular rate of from 310 to 313 beats per minute (fig. 1). Following the cessation of the attacks the heart maintained a rate of from 130 to 180 for the remaining ten days of life. Three weeks after the onset of the initial attack the infant died of streptococcic meningitis. An autopsy showed a grossly normal heart. Microscopically there was no evidence of infection or fibrosis, the only changes being terminal ones.

COMMENT

Sixteen cases of excessively rapid heart rates have been collected from the literature. These, together with the additional case that is being reported, are summarized in table 1. Only cases showing a rate of 280 beats per minute or over were included in the series.

TABLE 2.—Summary of Sex and Age Incidence

	Sex			Age			
	Male	Female	Not Stated	Under 2 Years	2 to 10 Years	10 to 20 Years	Over 20 Years
Number of patients	11	5	1	11	1	2	3

Cases⁵ in which the rate was described as "uncountable" or "too rapid to count," without an attempt to estimate the number of pulsations per minute, were omitted. Very rapid oscillations, as high as 1,000 per minute, have been recorded electrocardiographically in ventricular fibrillation.⁶ Cases of ventricular fibrillation, however, were omitted because of the transitory nature of the arrhythmia and the absence of ventricular pulsations during an attack. Cases⁷ of ventricular tachycardia in which the tachycardia was momentary and merely preliminary to, or terminating, an attack of ventricular fibrillation were also omitted. The criteria that were used to distinguish ventricular tachycardia from fibrillation were the persistence of heart sounds and pulse activity. Only one case of ventricular tachycardia with a rate approaching 300 was found to conform to these criteria.⁸

In this series of seventeen cases, the rapid heart rate occurred more frequently in males than in females in

the ratio of eleven to five, the sex of one patient not being stated (table 2). Two patients, both infants, were colored. The series is preponderantly one of infancy, eleven of the seventeen patients being under 24 months of age. Werley's¹ patient, in whom the onset of tachycardia occurred during the fourth day of life, was the youngest of the group. In Clarke's⁹ case an attack of tachycardia had its onset on the seventh day of life and persisted uninterruptedly for fifty-one hours. The longest duration of an attack was eight days, in an infant 2 months of age, reported by

TABLE 3.—Summary of Incidence of Associated Diseases

Age Groups	Associated Diseases					
	Not Stated	None Present	Diagnosis Undetermined	Infectious Diseases	Heart Disease	Exophthalmic Goiter
Under 2 years	1	3	3	3	1	0
2 to 10 years	0	1	0
10 to 20 years	..	1	..	1	0	0
Over 20 years	1	0	2

O'Flynn.¹⁰ The attacks of rapid heart action in the adult group were of comparatively short duration, five hours in Bunn's⁸ case and two hours in Blackford and Williams's² case. Mackenzie's¹¹ and Herapath's¹² patients had brief attacks of one-to-one response in auricular flutter, which usually presented a two-to-one block.

The diseases that were associated with the rapid heart action in the infant group show considerable divergence from those of the adult group (table 3). Three infants presented no symptoms at the onset or during the course of their attacks except those that were clearly produced by the arrhythmia itself. Three infants had an associated disease which was not diagnosed. In three cases in the infant group there was an infectious disease present prior to or during the onset of the rapid rate, in Koplik's¹³ case "grip," in de Bruin's¹⁴ case "probable encephalitis," and in the case being reported streptococcic meningitis proved at autopsy. In two cases in the adult group, infectious diseases in the form of typhoid and influenza had occurred prior to the onset of auricular flutter with two-to-one and three-

TABLE 4.—Summary of Incidence of Cardiac Arrhythmias

Blackford and Willius,² had established auricular flutter with two-to-one and three-to-one block and occasional paroxysms of one-to-one response, "usually following exertion." Bunn's⁸ patient had a single attack of paroxysmal ventricular tachycardia, which occurred thirty-six hours following thyroidectomy.

From a study of this series of cases it would appear that an excessively rapid ventricular rate is not an indi-

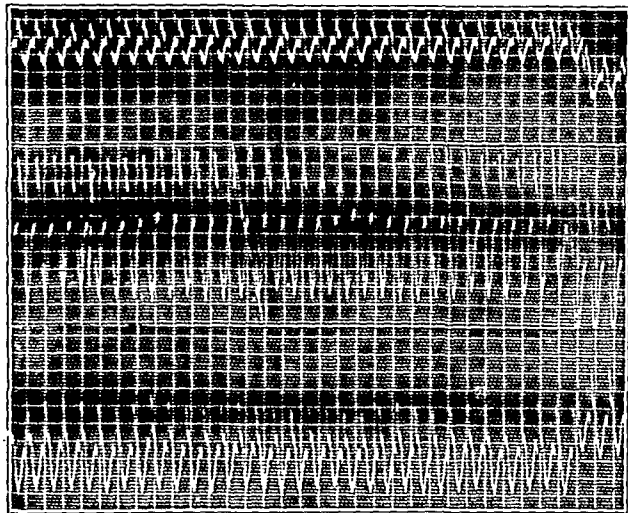

Fig. 1.—Electrocardiogram taken Feb. 19, 1934, the fifth day following the onset of the arrhythmia. The auriculoventricular rate is 310 beats per minute in leads 1 and 2 and 313 beats per minute in lead 3.

cation of heart disease. In only one instance was undoubted heart disease associated with the arrhythmia. Sachs¹⁶ reported the case of a 3 year old child, hospitalized for cardiac decompensation, who had a heart rate of 240 beats per minute when first examined. On the following day an electrocardiogram showed a rate of 280 per minute. A later tracing showed a three-to-one block and configuration suggesting auricular flutter. There were two subsequent attacks of rapid heart action two months and five months later with rates of 200 and 250 respectively. The child died a year after the initial attacks of tachycardia and seven months following the last attack. A postmortem examination showed diffuse subacute myocarditis with dilatation and hypertrophy of the heart. Russell and Ellison¹⁷ thought that congenital heart disease was present in their case of a child 15 months of age who had a rate of approximately 300 beats per minute over a period of five days. They stated that for the first four months of life the child had been entirely normal, with no clubbing of the fingers and no cyanosis present. The cyanosis that was observed during the first three days of the tachycardia did not persist, although the child's lips became blue when she cried. The authors cite the following observations obtained after the resumption of a normal heart rate: "The apex beat was in the fourth left intercostal space, a quarter of an inch internal to the nipple line. The right limit of cardiac dulness was at the right sternal edge. On auscultation the heart sounds were normal and a loud systolic murmur could be heard all over the left sternal edge over the fourth intercostal cartilage. There was no thrill." The nature of the congenital lesion was not determined. In Werley's¹ case a widely patent foramen ovale was found at autopsy, but at the

onset of the rapid rate there was also present an undiagnosed condition. The infant when examined on the second day of tachycardia, the fifth day of life, had a temperature of 102 F., dark-colored vomitus and stools, and numerous vesicles about the umbilicus, some containing reddish fluid. On the following day, the day of death, the heart rate varied from 150 to 160 beats per minute. At autopsy the heart was found to be normal except for the widely patent foramen ovale and congestion of the cardiac vessels.

The prolonged attacks of rapid heart action in the infant group were accompanied by surprisingly few evidences of cardiac embarrassment. O'Flynn's¹⁰ patient, whose rapid rate was maintained for eight days, retained her natural rosy color, nursed well and slept normally during the greater part of the attack. On the fourth day there was cyanosis at times, the heart and liver were enlarged and the urine was scanty. On the fifth day bronchitis developed with hepatic pulsations and Cheyne-Stokes breathing, but this complication did not prevent the complete recovery of the patient. In the case reported by Russell and Ellison¹⁷ there was a definite loss of consciousness for a few seconds just prior to the onset of a heart rate of 300 beats per minute. During the first two days of the tachycardia, which continued uninterruptedly for five days, cyanosis and restlessness were pronounced. These symptoms gradually abated, and during the last two days of the attack the child appeared well and happy. Clarke's⁹ patient, during a fifty-one hour attack of tachycardia, had good color when quiet, but at times, when crying or trying to nurse, the infant became very cyanotic and dyspneic and appeared to be extremely ill. At other times it was fairly comfortable and was able to nurse. Among the other infants there were varying degrees of cyanosis and dyspnea noted, as well as evidences of passive congestion. Duken's³ patient, an infant 8 weeks of age, went into an attack of syncope following the administration of 4 mg. of morphine. The heart rate dropped from 300 to 120 beats per minute, became

irregular, and then both the heart and respiration stopped. Intracardiac injections of epinephrine and cardiac massage were given and the heart resumed pulsations at a rate of from 100 to 120 per minute. In all the cases the symptoms of cardiac embarrassment cleared up quickly on the cessation of the arrhythmia. In the

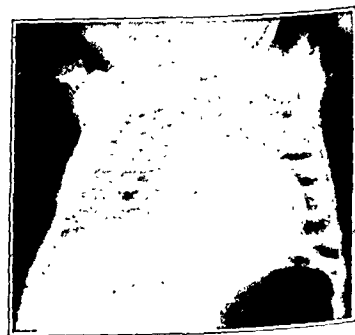

Fig. 2.—Teleroentgenogram taken February 23, the eighth day of recurring attacks of rapid heart action. The heart shows slight enlargement: M. R. 2.6 cm., M. L. 3.6 cm., thoracic diameter 10.8 cm.

adult group the attacks of rapid heart action, which of course were much briefer than those in the infant group, were well tolerated except in Bunn's⁸ case. His patient, an apprehensive individual, suffered a collapse at the onset of the rapid rate. The skin was cold and clammy, the pulse weak and the systolic blood pressure dropped from a normal of 138 to 60 mm. of mercury and the diastolic pressure from 70 to 40 mm. About five hours after the onset of the attack, pulmonary edema was present and the patient's condition seemed critical. On the cessation of the arrhythmia his condition improved

17. Russell, H. B., and Ellison, J. B.: A Case of Prolonged Tachycardia. Associated with Congenital Heart Disease, in a Child Fifteen Months Old. *Lancet* 2: 546-547 (Sept. 10) 1927.

rapidly. Blackford and Willis's² patient was not sufficiently inconvenienced during the first hour of her attack to comment about it. She walked several blocks and climbed one flight of stairs during the two hour duration of the rapid rate.

There were three deaths in the series. In Werley's¹ case the tachycardia may have been a contributing cause of death. In the other two cases it is unlikely that the rapid rate was a determining factor in the outcome, as one patient died of heart disease seven months, and the other of streptococcic meningitis ten days, after the final attack of tachycardia. In one case the outcome was not stated. In the remaining thirteen cases (76 per cent) there was a resumption of the normal rate. The prognosis, therefore, in cases of excessively rapid heart rate appears to be good unless an associated condition is present that cannot be controlled. It should be borne in mind that long continued auricular tachycardia of rapid rates or frequent paroxysms of one-to-one response in established auricular flutter constitute a grave burden when the circulation is already inefficient because of a diseased heart muscle. This series of cases, however, shows that excessively rapid rates, such as those under discussion, occur in patients with relatively sound heart muscles. The observations in this series also bears out the statement frequently made that there is greater responsiveness of the conduction system and greater elasticity of the musculature in the hearts of very young children. They therefore tolerate prolonged attacks of rapid heart action and make a quick, and apparently a complete, recovery on the resumption of a normal rate.

In eleven cases collected from the literature, rates of approximately 300 beats per minute were diagnosed as paroxysmal tachycardia of auricular origin (table 4). This greatly exceeds the upper limit of 220 beats per minute which Lewis¹⁸ set for paroxysmal auricular tachycardia. It will be noted, however, that with two exceptions the arrhythmias diagnosed as auricular tachycardia occurred in very young children. In only four of these cases was an electrocardiogram published showing the arrhythmia. Colgate and McCulloch,¹⁹ who published a tracing showing a rate of 291 beats per minute in a case of an infant 3½ weeks of age, stated: "Whether the case reported here should be diagnosed as auricular flutter or paroxysmal tachycardia is uncertain. The criterion by which these two conditions may be differentiated is by no means clear." Farr and Wegman²⁰ also were uncertain as to the interpretation of the tracing in their case of an infant 5½ weeks of age who had a rate of 300. "The electrocardiographic tracings," they contended, "do not permit of an accurate distinction between auricular tachycardia and auricular flutter with one-to-one rhythm. . . . In an adult the rate would make a diagnosis of flutter almost certain, but when one considers the rapidity with which a normal infant's heart may beat when the child is crying, one must admit that a higher limit ought to be postulated for paroxysmal tachycardia in infants." Wilson,²¹ in a summary of cases of rapid heart rates in children, recognized the difficulty of distinguishing between the two arrhythmias. "Both auricular flutter and paroxysmal tachycardia," he said, "have been

observed in children, but there is some confusion as to the separation of the two conditions at this period of life. The reason for this is that in children the auricular rate may often exceed 200 per minute without any block being present and moreover the attacks of very rapid auricular action so far observed in children have all been of comparatively short duration." He did not attempt to distinguish between the two conditions but referred to both as "auricular tachysystole." Lewis²² published an electrocardiogram showing a rate of 290 beats per minute in a child 3 months of age and interpreted the arrhythmia as auricular flutter with a one-to-one rhythm. Among the cases collected from the literature in this series, all other instances of auricular flutter occurred in adults. In these the diagnosis was indisputable, as in each the established rhythm prior and subsequent to the paroxysms of one-to-one rhythm was auricular flutter with block. One case, occurring in an adult, was diagnosed as ventricular tachycardia. Bunn,⁸ who reported the case, expressed doubt as to the correctness of his interpretation and discussed the possibility of its being auricular flutter with one-to-one rhythm.

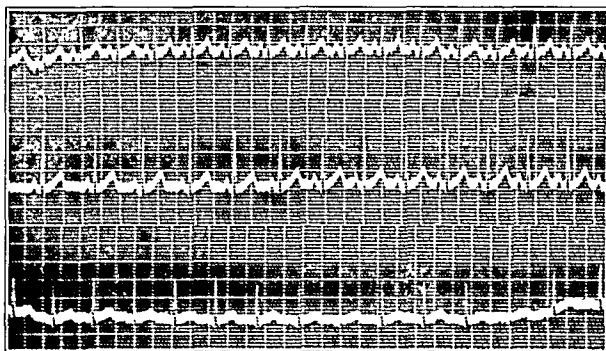

Fig. 3.—Electrocardiogram taken March 3, showing an auriculoventricular rate of 130 beats per minute. Aside from the tachycardia, the tracing is normal.

Interpretation of Electrocardiogram.—The arrhythmia presented in the electrocardiogram with a rate of 310 to 313 beats per minute in the case being reported is interpreted as paroxysmal auricular flutter with one-to-one response and intraventricular block due to fatigue of the heart muscle (fig. 1). Because of the extreme rapidity of the rate, the bizarre character of ventricular complexes and the absence of the onset or offset of the paroxysms it is impossible to be dogmatic about the interpretation of the tracing. Not only is paroxysmal auricular tachycardia a possibility but, owing to the aberration of the QRS complexes, paroxysmal ventricular tachycardia must also be considered. A study of the cases of excessively rapid heart rates collected from the literature revealed the difficulties of interpreting such arrhythmias. In an attempt to determine whether any unanimity of opinion existed concerning their interpretation, copies of the electrocardiogram were submitted to a number of the leading cardiologists in America and Europe. Eleven cardiologists in America and eight abroad gave unqualified agreement to the diagnosis of paroxysmal auricular flutter with one-to-one block and intraventricular block due to fatigue of the heart muscle. Six additional American cardiologists thought that the interpretation was probably correct but that some other diagnosis could not be ruled out with

certainty. Six American cardiologists interpreted the arrhythmia as paroxysmal ventricular tachycardia and one as paroxysmal auricular tachycardia. To several the marked regularity of the tracing spoke against its being ventricular tachycardia; to others the distortion of the ventricular complexes in leads 1 and 2 suggested a tachycardia of ventricular origin. Some thought that the only mechanism that would cause so rapid a rate was auricular flutter; others that rates as high as 300 were possible in paroxysmal tachycardia in children. One cardiologist had observed similar records in experimental animals when the evidence pointed to its being paroxysmal tachycardia.

SUMMARY

1. An infant, 4½ weeks of age, at the onset of a fatal attack of streptococcic meningitis showed a heart rate of from 310 to 313 beats per minute, recorded electrocardiographically. Autopsy revealed a grossly normal heart. Microscopically there was no evidence of infection or fibrosis of the heart muscle.

2. Sixteen cases having heart rates of approximately 300 beats per minute were collected from the literature.

3. As the interpretations of very rapid rates in young children in this series presented considerable uncertainty, the electrocardiograms showing a rate of 310 to 313 beats per minute in the case being reported was submitted to a number of eminent cardiologists for their opinion.

CARCINOMA OF STOMACH IN A CURED CASE OF ADDISON-BIERMER'S (PERNICIOUS) ANEMIA

I. W. HELD, M.D.

Attending Physician, Beth Israel Hospital; Clinical Professor of Medicine, New York University College of Medicine

AND

A. ALLEN GOLDBLOOM, M.D.

Associate Physician, Beth Israel Hospital and Metropolitan Hospital; Associate Cardiologist, Beth Israel Hospital, and Instructor in Medicine, New York Medical College

NEW YORK

Whereas a great number of cases have been reported of Addison-Biermer's (pernicious) anemia associated with cancer, in the pre-liver era as well as since the institution of liver treatment for this condition, the literature contains very few reports of authentic cases in which all the symptoms of anemia had disappeared, following which cancer of the stomach developed. In view of this rarity we are reporting a case in which a male patient developed Addison-Biermer's anemia in 1927, was completely cured by liver treatment, and recently developed cancer of the stomach.

REPORT OF CASE

J. K., a man, aged 63, married but without children, seen in March 1924, complained of indefinite gastric symptoms. A thorough gastro-intestinal roentgen examination at the time was negative. Examination of the stomach contents showed an absence of free acidity, a low total acidity and no lactic acid. The gastric symptoms were attributed to an unexplained achlorhydria. There was no clinical evidence of anemia.

In the spring of 1928 the patient returned. He had felt well until the fall of 1927, when he began to experience marked weakness, inability to work, mental depression and severe epigastric pain.

In the four years that had elapsed his hair had become almost white and his skin waxen, with a hemic pallor.

Physical examination at this time revealed a short systolic murmur over the apex. The blood pressure was 120 systolic, 80 diastolic.

The spleen was barely palpable. The panniculus adiposus was well retained. The abdominal and knee reflexes were absent. The weight was 107 pounds (48.5 Kg.).

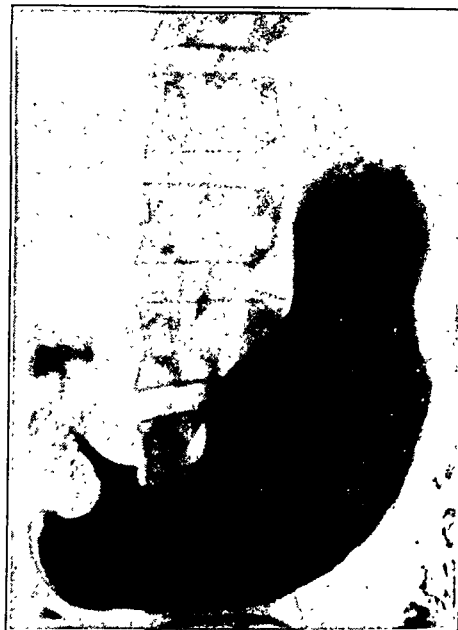

Fig. 1.—Defect in pylorus in a four-hour gastric roentgen examination. The rugae are not visible with this mixture.

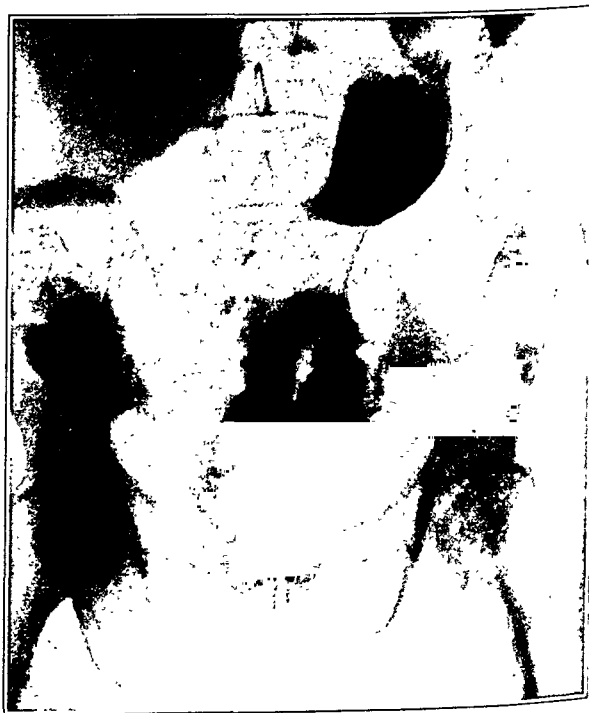

Fig. 2.—Marked residue (forty-eight hours) in a stenosing carcinoma of the pylorus. Barium in large intestine after evacuation of contrast enema.

Examination of the blood revealed hemoglobin 50 per cent, red blood cells 2,610,000, color index 0.9. The differential blood smear showed polymorphonuclears 60 per cent, lymphocytes 26 per cent, myelocytes 3 per cent, monocytes 10 per cent and transitionals 1 per cent.

The gastric contents showed an absence of free hydrochloric acid, total 15. The lactic acid was negative. The blood serum was dark yellow, bilirubin 0.9, icterus index 6. The blood picture was that of Addison-Biermer's anemia, except for the fact that the color index was below 1. The blood Wassermann

X-ray examination of the gastro-intestinal tract showed a definite deformity of the pylorus (fig. 1) and marked gastric catarrh, with a forty-eight hour residue (fig. 2). In view of a diagnosis of stenosing carcinoma of the pylorus, surgical intervention was deemed urgent.

Accordingly the patient was operated on February 21 by Dr. A. A. Berg at the Mount Sinai Hospital, a gastric resection being performed for carcinoma of the pylorus. There was a defect in the mucosa, with thickened mucosal folds, as seen in the resected stomach (fig. 4). The pathologic report by Dr. Paul Klemperer was ulcerated infiltrating adenocarcinoma of the stomach, with involvement of the omentum; no involvement of the lymph nodes; hyperplastic catarrh of the stomach (fig. 5).

The patient was examined Nov. 2, 1936, nine months following the operation. He had gained 15 pounds (7 Kg.) and had a very good appetite. The rest of the physical examination was negative.

The hematologic examination showed hemoglobin 89 per cent, red blood cells 4,400,000 and color index of 1.01. The differential count showed segmented cells 72 per cent, small lymphocytes 22 per cent, eosinophils 2 per cent, mononuclears 3 per cent and large lymphocytes 1 per cent. The individual cells were practically normal with no variation in size, shape or stain.

The roentgenogram (fig. 6) showed a postoperative stomach with a patent lumen and rapid emptying time. There was no evidence of any metastasis.

COMMENT

That cancer of the stomach, or of any part of the gastro-intestinal tract, especially of the cecum, may hematologically simulate Addison-Biermer's (pernicious) anemia is very well known, and it is also true

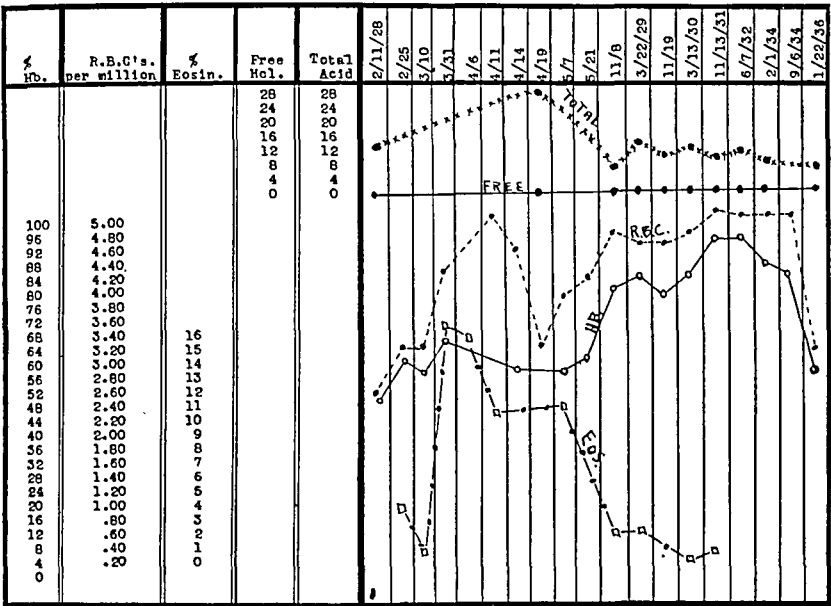

Fig. 3.—Constancy of absence of free acidity and response of blood to liver therapy.

reaction was negative. Roentgen examination of the gastro-intestinal tract was negative.

The condition was diagnosed as Addison-Biermer's anemia and the patient was placed on the regular regimen for such cases of diluted hydrochloric acid and liver extract. The sequence of events in this case as to the progress may be noted from the chart, showing the various blood counts up to the period of 1930 (fig. 3). The case was reported by us in 1931 because of the peculiar reaction encountered.¹

While under liver extract therapy for about a month, the patient reported to us in the office because of symptoms of renal colic and showed a peculiar skin reaction. It was considered that the passage of excessive uric acid crystals explained the renal colic. An urticaria and erythema nodosum with marked itching and pain in the right knee joint were present. Analysis showed an increased uric acid of 4.2 mg. per hundred cubic centimeters of blood (fig. 3). The blood showed a large number of disintegrated white blood cells and eosinophils. The patient was under continuous observation, improving in both symptomatology and weight. The blood returned to a normal state (fig. 3).

In January 1936 the patient complained of loss of weight, appetite and weakness, with inability to enjoy his meals for the past six months. He had occasional attacks of vomiting and regurgitation of food, with a sensation of sourness in the mouth. On several occasions hematemesis occurred.

The physical examination revealed that the patient had lost some weight. His complexion was paler than before and there was pronounced weakness. Palpation showed slight resistance in the epigastrium with a suggestive mass. The blood pressure was 140 systolic and 80 diastolic. Examination of the blood showed hemoglobin 60 per cent, red blood cells 3,200,000 with a color index of 0.93, and white blood cells 7,200. The differential blood smear showed segmented cells 60 per cent, small lymphocytes, 30 per cent, large lymphocytes 4 per cent, eosinophils 2 per cent and mononuclears 4 per cent. There was slight anisocytosis with no predominance of macrocytes. The gastric contents showed free acidity 0, total 10, with occult blood in both stool and stomach contents. It was impossible to perform a fractional test meal because of the marked retention of food.

Fig. 4.—Resected stomach showing thickened mucosa with definite malignant condition in the pylorus. (Obtained through the courtesy of Drs. A. A. Berg and Paul Klemperer.)

that Addison-Biermer's anemia may be associated with cancer, so that it is impossible to determine which was primary. There have been encountered, however, only a few cases in which the hematologic picture and

1. Held, I. W., and Goldbloom, A. (1931) Pernicious Anemia: Report of a Case Showing Response to Liver Extract, J. A. M. A. 96: 1361-1363

symptoms of Addison-Biermer's anemia entirely disappeared as a result of treatment, after which carcinoma of the stomach developed. Strandell² reported in 1931 two cases out of 117 cases, or 1.7 per cent, of cured pernicious anemia. Since then Wilkinson³ has reported 370 cases with or without symptoms of collateral involvement of the spinal cord, in two of which (0.054 per cent) gastric cancer developed after successful treatment of the pernicious anemia, five years prior to the onset of the carcinoma. Conner and Birkeland,⁴ in 658 patients with pernicious anemia at the Mayo Clinic, found that in four, or 0.6 per cent, carcinoma developed when they had been on specific therapy for a period of seven or eight years and had recovered from this condition. Murphy⁵ in his own series states: "In analyzing 440 cases of pernicious anemia only four instances of associated carcinoma of the stomach were found (0.9 per cent). Three of these were adenocarcinoma and the other was carcinoma of the pyloric region."

Although liver treatment is effective in Addison-Biermer's anemia so far as returning the hematologic picture to normal is concerned and may also bring about complete disappearance of the subjective symptoms, the existing anacidity, which is a constant feature of the disease, may continue, as may neurologic manifestations, if these were present. Therefore there are certain authors who are of the opinion that the anacid gastritis is a predisposing factor for the development of gastric cancer. Judging, however, from the very few occurrences of cancer in cured cases of Addison-Biermer's anemia, it is scarcely conceivable that the cancer is at all the result of the persistent anacidity. It is, in all probability, a mere coincidence.

However, it is important, when an individual who has recovered from Addison-Biermer's anemia develops

not to conclude arbitrarily that the condition is a recurrence of Addison-Biermer's anemia. Before such a diagnosis is reached a thorough examination of the gastro-intestinal tract should be made to rule out gastric carcinoma as an independent cause of the anemia. It is also important not to regard the degree of anemia.

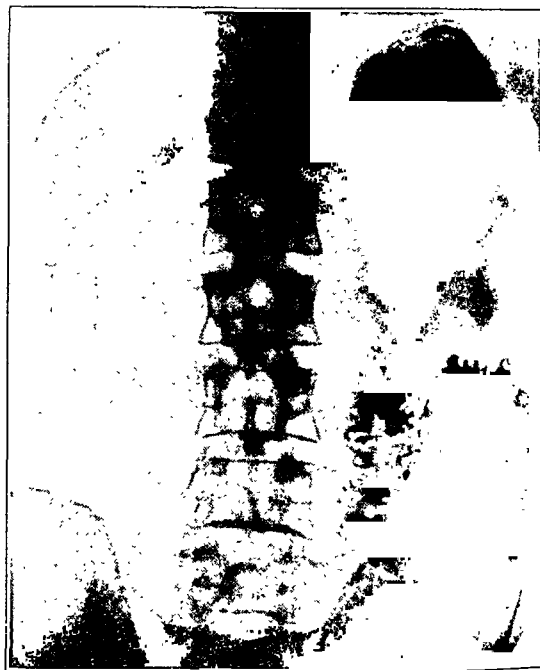

Fig. 6.—Stomach after operation showing patent lumen and rapid emptying with hyperperistalsis and hypermotility.

when cancer is the cause, as a contraindication to surgery, for in many cases successful removal is possible and life may be indefinitely prolonged.

SUMMARY

1. In the event of recurrence of symptoms and hematologic signs of Addison-Biermer's anemia or secondary anemia after the cure of Addison-Biermer's anemia, differential diagnosis between actual recurrence and an independent cause of the anemia, such as gastric carcinoma, must be made.

2. Successful removal of the lesion may be possible, in spite of the anemia.

2 East Ninety-Fifth Street—65 East Ninety-Sixth Street.

Countless People Contribute.—Every hospital recognizes more or less clearly its set obligations; what helps or hinders most of their fulfillment are the crystallized traditions which give an institution its particular individuality. In the development of this quality countless people, however unconsciously, have contributed—those whose charity has given comfort and peace of mind, as well as those whose professional skill has brought physical well being to the maimed and sick; those who have brought the greatest sympathy and understanding to the problems of the young people here to learn; those who may never have come in special contact either with patients or with students but, freed from the killing routine of the clinic, have applied themselves to the forwarding of knowledge; those who have managed the business affairs of the hospital and its relations to the outside world; those, too, who have made the beds, kept the books, answered the phone, cooked the food, done the wash, stoked the fires, scrubbed the floors and killed the rat—in the hospital Jack built.—Cushing, Harvey: *Consecratio Medici and Other Papers*, Boston, Little, Brown & Co., 1928.

GRANULOMA VENEREUM OF CERVIX
UTERI (GRANULOMA INGUINALE)
SIMULATING CARCINOMA

EDGAR R. PUND, M.D.

AND

ROBERT B. GREENBLATT, M.D.

AUGUSTA, GA.

A clinicopathologic study of granuloma inguinale has enabled us to describe its specific histologic picture.¹ This characteristic pathologic appearance was determined by the study of sections of tissue taken from lesions in which the Donovan bodies had previously been demonstrated in films.

We have recently observed two patients with granulomatous growths of the cervix that exhibited the specific histologic picture of granuloma inguinale. It is interesting to note that in these two cases epithelioma was suspected clinically. This suspicion was so strong in one instance that a radium pack was applied at the time of biopsy. From these observations we are enabled to report a heretofore disregarded entity. However, Gardner² has briefly suggested that granuloma of the cervix may possibly be related to granuloma inguinale. Because lesions of this specific disease, commonly called granuloma inguinale, have now been observed at sites other than the inguinal region, we prefer the term granuloma venereum. We are therefore placing on record and describing a lesion which, to differentiate from cancer of the cervix, challenges the diagnostic acumen of the clinician. Histologic differentiation offers little difficulty. A knowledge of the microscopic picture permits the pathologist to render a specific diagnosis in these cases, which hitherto have been dismissed with the sententious but noncommittal description "nonspecific granulation tissue."

REPORT OF CASES

CASE 1.—A Negress, aged 33, a tertipara, was referred to the cancer clinic of the University Hospital because of a fungating growth involving the whole cervix. She gave a history of intermenstrual bleeding for three months and daily spotting for the past three weeks. Dr. G. T. Bernard, chief of the cancer clinic, examined the patient and described the condition as follows: "The cervix presents a large papillary growth, round in contour without surrounding infiltration. The finger can readily encircle the cervix. The surface of the growth is granular and red in appearance and does not bleed when gently sponged. The central portion is ulcerated. The fundus of the uterus is freely movable, but the lower uterine segment appears to be slightly fixed." Biopsy was taken and 3,000 mg. hours of radium was given. The granulomatous lesion disappeared within several days. When last examined, one month after treatment, a few minute residual ulcers and a diffuse pin point nodularity were present. The Wassermann reaction on the blood was four plus. The Frei test was positive. She also reacted positively to both the chancroidal bacillary and pus antigen tests.

The pathologic report of the biopsy was: Granuloma inguinale of the cervix uteri. The "pathognomonic cells" are very numerous throughout the sections. There is no evidence of malignancy (fig. 1).

CASE 2.—A Negress, aged 18, five months pregnant, was found on examination at the university clinic to have a clean, raised, circumscribed tuft of reddish granular tissue measuring 3 by 2.5 by 1 cm., situated at the left border of the

vulva and fourchette. The cervix was freely movable and exhibited a soft velvety red lesion covering the whole anterior lip and the right half of the posterior lip. There was no adnexal induration or involvement of the vagina. Numerous Donovan bodies were demonstrated in films from both the cervical and the vulvar lesions. Only a few other organisms were found. Biopsies were taken from the cervix and vulva. The Wassermann reaction on the blood and the Frei test were negative. The intradermal chancroidal bacillary and pus antigen tests were positive. She is responding to fuadin therapy.

The pathologic report on biopsies was: Granuloma inguinale of the cervix and vulva. Sections from both lesions reveal the "pathognomonic cells" in abundance (fig. 2).

COMMENT

The histologic picture of sections from these two cases conforms to our previous description, a summary of which is here included:¹

The essential features are the massiveness of the cellular reaction in which the luxuriant granulation tissue is surcharged with plasma cells; the relative paucity of lymphocytes; the diffuse sprinkling of polymorphonuclear leukocytes with focal collections in the superficies . . . ; the pathognomonic large mononuclear cells scattered in various numbers throughout the granulation tissue. This pathognomonic cell is specific for

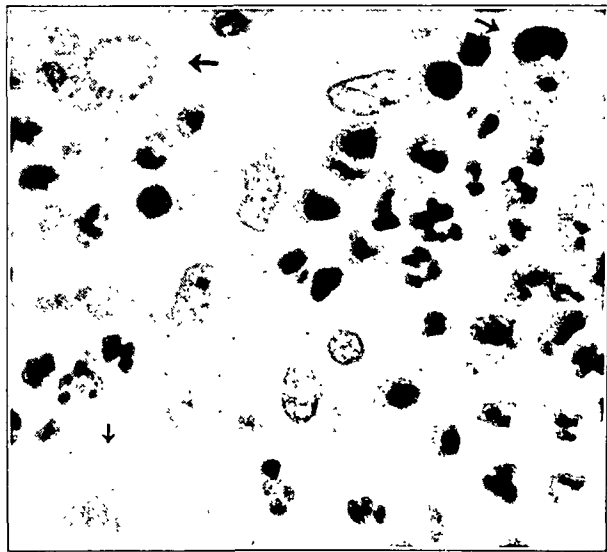

Fig. 1 (case 1).—Section from lesion of cervix. Note the characteristic cell of granuloma inguinale and the arrangement of the bodies within the intracytoplasmic cysts (upper left). Two other cells, not in focus, are indicated by arrows. Hematoxylin and eosin. Slightly reduced from a photomicrograph with a magnification of 1,440 diameters.

granuloma inguinale. The relatively large size of the cell, which varies from 25 to 90 microns, and the presence of many intracytoplasmic cysts filled with deeply stained bodies are its cardinal features. These bodies are round or rodlike, are grouped peripherally within the cysts and have an affinity for hematoxylin.

In addition to this description we have a further contribution to make. We have observed in sections that the so-called Donovan bodies have an affinity for silver salts. The use of the silver impregnation method of Dieterle³ facilitates the demonstration of the specific cell laden with these bodies. The cell outline, nucleus and cyst walls stain pale yellow, while the Donovan bodies appear as dark brown or black rectangular or elongated ovoid forms with intense bipolar staining. These bodies, because of their contour and polar characteristics, resemble a safety-pin (fig. 2).

3. Dieterle, R. R.: Method for Demonstration of *Spirochaeta Pallida* in Single Microscopic Sections, *Arch. Neurol. & Psychiat.* 18: 23 (July) 1927.

DIFFERENTIAL DIAGNOSIS AND CLINICAL
DESCRIPTION

Granuloma venereum of the cervix is characterized by a moderately clean tuft of reddish meaty tissue, abruptly raised above the surface and with well defined borders. The lesion has a peculiar resilience, is velvety soft to palpation and does not bleed easily on touch.

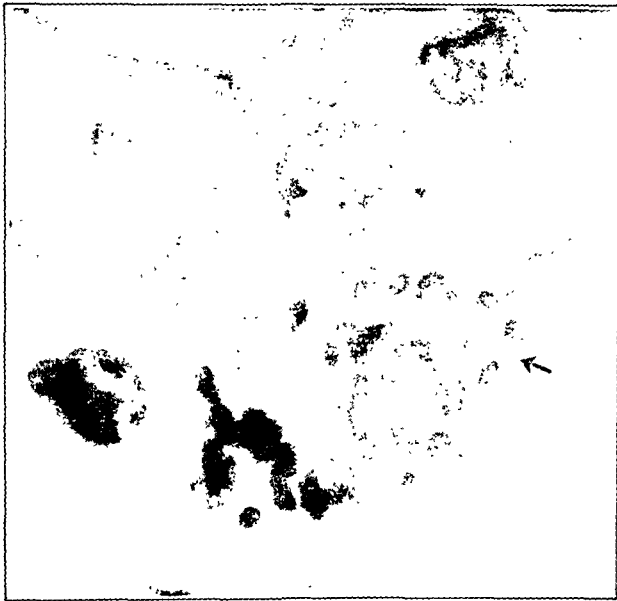

Fig. 2 (case 2).—A pathognomonic cell in a section from the cervix stained by Dieterle's silver technic. Note the characteristic safety-pin appearance of some of the intracyclic bodies. Slightly reduced from a photomicrograph with a magnification of 3,500 diameters.

However, the growth may become markedly exuberant, fungating and ulcerative. The cervix alone may be involved, as in case 1, or the disease may be manifest elsewhere, as in case 2. Nonetheless the lesion of the cervix presents itself as an entity that must necessarily be differentiated from both the ulcerative and the vegetative type of carcinoma of the cervix. Malignant growths of the cervix have a friable hardness which can frequently be broken up with the finger. The various manifestations of cervical endometritis, such as polypoid hyperplasia and eversion, should be borne in mind. Cervical endocervicitis, whether due to gonorrhea, nonspecific infection or erosion, may sometimes offer difficulties in the differential diagnosis. A primary chancre, tertiary syphilis or a chancroidal lesion do not uncommonly involve the cervix. Tuberculosis of the cervix is rather rare. In the final analysis the diagnosis of these conditions must be determined by histopathologic study of biopsies.

SUMMARY AND CONCLUSIONS

1. A heretofore unrecognized entity, granuloma venereum of the cervix (granuloma inguinale), clinically simulates carcinoma of the cervix.

2. Since the involvement by the Donovan body occurs elsewhere than in the groin and on the external genitalia, the name of granuloma venereum is preferable.

3. It is characterized clinically by a tuft of reddish meaty tissue, raised above the surface, clean in appearance, velvety soft and resilient to palpation, and it does not bleed readily to touch.

4. Histopathologically, the essential features are the exuberant granulation tissue reaction in which the

pathognomonic cell is found. This cell is a large mononuclear cell with intracytoplasmic spaces in which are dispersed the so-called Donovan bodies.

5. The affinity of the intracyclic bodies for silver salts facilitates the recognition of the characteristic cell. With silver these bodies are stained black to brown and have a safety-pin appearance because of their elongated ovoid outline and intense bipolar staining reaction.

HYPERINSULINISM ASSOCIATED WITH
CALCIFIED TUMOR OF THE
PANCREAS

WITH SURGICAL CURE

S. F. HERRMANN, M.D.

AND

JOHN A. GIUS, M.D.

TACOMA, WASH.

Soon after the discovery of insulin in 1923, Banting and his associates¹ noted the manifestations of hypoglycemia when the blood sugar fell below 0.07 per cent under the influence of insulin. They described the typical symptoms, which are familiar today to all who have used insulin, and observed that the condition was relieved by administration of carbohydrate and avoidance of excessive doses of insulin. The condition termed "spontaneous hyperinsulinism" was first suggested by Seale Harris² in 1923, and he reported five cases in 1924. In 1926 Warren³ reported fifteen cases of islet cell tumors from the literature and added four more. The significance of these tumors was not proved until 1927, when Wilder and his associates⁴ demonstrated a definite pathologic basis for hypoglycemia due to hyperinsulinism. At operation a pancreatic carcinoma with metastases to the liver, regional nodes and mesentery was found. Autopsy showed that these lesions were composed of cells closely resembling islet cells. Extract of a liver nodule was said to act like insulin when injected into rabbits.

The first successful operative removal, credited to Roscoe Graham, was reported by Howland and his associates⁵ in 1929. Subsequently some thirty successful cases have appeared in the literature. Washington

University surgeons have contributed five cases.⁶ Bast, Schmidt and Sevringhaus⁷ reported the successful removal of a carcinoma of the islands of Langerhans for status epilepticus due to hyperinsulinism, and Whipple and Frantz⁸ in a comprehensive review reported six cases of pancreatic adenomas successfully operated on at the Presbyterian Hospital in New York during 1934-1935. Space will not permit the enumeration of all the cases; suffice it to say that surgical treatment of this type of lesion has been very gratifying.

The symptoms, as originally described by Banting, Campbell and Fletcher,¹ consist of nervousness, tremor, hunger, anxiety, sweating, fatigue, emotional instability, incoordination of the finer movements, vasomotor phenomena such as pallor and flushing, confusion, difficulty of articulation, syncope, collapse and unconsciousness. Convulsions may be added to this list. Recently the gastro-intestinal manifestations of hyperinsulinism have been studied by Harris.⁹ He points out the frequency with which it simulates peptic ulcer, irritable colon, cholecystitis, appendicitis, pancreatitis and especially the group of cases now classified as neuroses of the stomach, intestine and other abdominal viscera.

The fact that the symptoms are frequently so protean and indefinite has resulted in many of the cases being labeled idiopathic epilepsy, alcoholism, neurasthenia and the like before the hypoglycemia has been discovered. It must be true that many of these cases are never diagnosed, and to correct this Harris advocates routine fasting blood sugar estimations on all patients.

It is to be recalled that spontaneous hypoglycemia is merely a descriptive term and denotes a lowering of blood sugar below normal limits. This condition may be due to a variety of causes and is not to be confused with hyperinsulinism. Wauchope¹⁰ has listed the causes of hypoglycemia:

1. Excess of insulin due to therapy, tumors, hyperplasia or functional hyperinsulinism.
2. Lack of opposing secretions which may result from disease of the suprarenal glands, tumors of the anterior or posterior lobe of the pituitary or myxedema.
3. Lack of glycogen resulting from destruction of reservoirs, disease of the liver, or wasting of muscles, abnormal secretion of sugar in starvation and intoxication from phosphorus or arsenamine poisoning.
4. Interference with regulating centers may result from disease affecting the pons or overactivity of the vagus nerve.

Holman¹¹ has described three surgical conditions recorded in the literature as being responsible for hyperinsulinism resulting in hypoglycemia:

1. Metastatic tumors or carcinomata of the islets of Langerhans which contrary to usual carcinoma of secreting glands have retained their property of producing insulin.
2. A benign tumor or an adenoma of the islets comparable to an adenoma of the thyroid.

11. Holman, E., and Railsback, O. C.: Partial Pancreatectomy in Chronic Spontaneous Hypoglycemia, *Surg., Gynec. & Obst.* **56**: 591 (March) 1933.

3. An overactivity of an otherwise normal appearing pancreas comparable, as pointed out by Wilder, to hyperthyroidism due to hyperplasia.

All three of these conditions have been subjected to surgical intervention with amelioration and in some cases complete cure. The most frequent condition reported and the most remarkable results have been in group 2. Surgical resection in group 3 has been disappointing.

Pancreatic lithiasis is a relatively rare condition. Nine cases had been reported at the Mayo Clinic¹² before 1934. Seeger¹³ was able to collect 100 cases from the literature in 1924. In most cases the stones are eccentric and occupy the cortex or an accessory pancreatic lobe. Usually they produce no obstruction and no symptoms. In a case reported by Rienhoff and Lewis¹⁴ a pancreatic calculus which had caused an acute pancreatitis was found at operation to be impacted in the pancreatic duct. There is no mention of hypoglycemia. In case 5 of Whipple and Frantz's series there were two tumors in the body of the pancreas. A third of one of these was calcified and both tumors showed extensive degeneration and fibrosis.

The frequency with which degeneration occurs in islet cell tumors has been noted as well as the apparent lack of correlation existing between the size and microscopic appearance of the tumor and the severity of the hypoglycemia.¹⁵

In the present case, hyperinsulinism of a marked degree associated with a pancreatic calculus without gross adenomatous islet tissue is reported. The fact that clinical cure followed surgical removal seems to establish the etiologic relationship. It is possible, however, that tumor tissue of microscopic proportions was destroyed at operation. On the other hand, the mechanism of the production of hyperinsulinism on the basis of a seemingly inert foreign body in the head of the pancreas has not been adequately explained on a physiologic basis. This subject is to be investigated further.

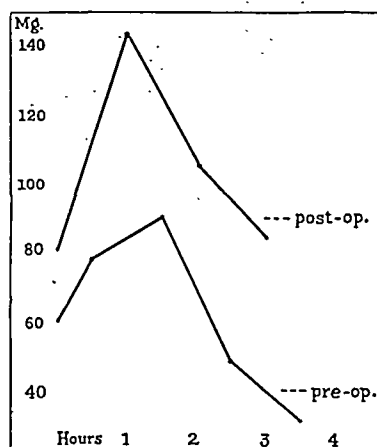

Fig. 2.—Dextrose tolerance test (average figures).

REPORT OF CASE

History.—C. H., a white man, aged 48, admitted to the Pierce County Hospital Aug. 13, 1935, complained chiefly of "weakness." In 1923 the patient first noted a constant sensation of chilliness in spite of increased clothing, warm weather and increased activity. Several years later he began having rather severe headaches, which seemed to originate in the neck, radiating into the occipital and frontal areas, accompanied by marked general weakness. These headaches would often appear

15. Frantz, V. K.: Personal communication to the authors.

suddenly, persist for a few hours and then decrease in intensity, but usually they remained as a pressure sensation for several days. About this time the patient also experienced vertigo and blurring of vision, especially on severe exertion. Frequently this resulted in collapse. However, there was at no time loss of consciousness or convulsive movements. Occasionally the patient observed marked tremors of the extremities and fibrillary muscle twitching.

Dyspnea on exertion without apparent cardiac distress later became prominent, and the patient was rendered almost totally incapacitated. In spite of a good appetite and no particular food idiosyncrasies, he lost weight amounting to about 35

3½ hr.....	33.0 mg.		

* 100 Gm. dextrose was used as the standard dose.

pounds (16 Kg.) over a period of three years. No abnormal appetite for carbohydrates was noted. A very evident emotional instability was manifested, especially by the patient's inability to get along with others and also by his extreme annoyance at trivialities. He had no pain and no digestive symptoms but complained of a more or less constant sensation of heaviness in the epigastrium. At no time was there polydipsia or polyuria, and nocturia occurred infrequently.

The patient had always enjoyed good health previous to the onset of the present illness. He had had measles, whooping cough and smallpox in childhood, malaria in 1910 and influenza in 1928, from which he recovered with no apparent complications. There had been no accidents and no previous operations. He drank two or three cups of coffee daily and used tobacco and alcohol infrequently. He had been taking acetylsalicylic acid for headache with some relief.

He was born in Kansas but had lived in Washington for the past twenty years and had worked as a plasterer for thirty-five years.

The family history was irrelevant. One sister had Bright's disease and goiter. There was no history of diabetes mellitus.

Physical Examination.—The temperature was 98.6 F., the pulse 72, the blood pressure 120 systolic, 90 diastolic, and the respiration rate 18. He was pale, rather weak and quite thin and he seemed to be mentally alert. He was quite gray for his years. There were no evident cranial defects. The pupils reacted normally. The fundi were normal. Dentures were

9/ 8/36.....	115.0 mg.

present. The thyroid was slightly enlarged but free of nodules. Chest expansion was normal. The lung fields were clear. The heart was essentially normal. The abdomen was flat and there were no masses or points of tenderness. The liver was at the costal margin. The spleen was not enlarged. There was a slight tremor of the outstretched fingers.

The basal metabolic rate was plus 1. October 3 the urinalysis showed specific gravity 1.015, very acid, albumin 0, reduction 0, acetone 0. Occasional pus cells were present. Hemoglobin was 92 per cent (Dare); red blood cells numbered 4,660,000; the color index was 1. White blood cells numbered 9,400, polymorphonuclear leukocytes 68 per cent, small lymphocytes 25 per cent, monocytes 6 per cent, basophils 1 per cent. The sputum was negative for acid-fast organisms. The blood sugar October 28 (Folin-Wu method) was 63.3 mg. per hundred cubic centimeters of blood. The result of the dextrose tolerance test is given in table 1.

The Wassermann reaction was negative. X-ray examination of the chest showed heart and lungs within normal limits. No x-ray examination of the abdomen or skull was made. No blood amylase estimation was done.

Progress in Hospital.—A diagnosis of hypoglycemia of unknown origin was made. The patient improved symptomatically on bed rest and a high carbohydrate diet. He was discharged to the outpatient department, where he was followed until April 30, 1936, when he was readmitted to the hospital.

During the interim the patient consumed large quantities of carbohydrates at frequent intervals. He estimated that he had spent \$70 in four months for hard candy alone. Although he had gained weight, felt somewhat stronger and was able to be up and about most of the time, he did not have sufficient energy to perform any sort of manual labor. It was observed that a marked psychoneurotic attitude had developed, which confused the picture somewhat and placed some doubt on the possibility of his multiple symptoms being due to a single etiologic factor.

Operation and Result.—Exploratory laparotomy for a possible pancreatic tumor was performed May 4 under ether anesthesia. A vertical incision to the left of the umbilicus was made. The greater omental bursa was opened below the stomach and the pancreas was exposed. The body of the pancreas was entirely normal but a tumor was palpated in the head, so that the approach was changed. The duodenum was mobilized by cutting the lateral peritoneal reflexion. The pelvis of the gallbladder was dissected up from the common duct, and the common duct then was exposed behind the duodenum and retracted so that the tumor could be removed from the head of the gland. This was done by surgical cautery, and oozing was controlled by electrocoagulation. A strip of plain gauze

packing was placed in the area of resection and was surrounded by plain rubber tissue, which was brought out through the upper end of the incision. The abdomen was closed in the usual manner.

A hard calcareous tumor was embedded in the head of the pancreas (fig. 1). It measured about 2.5 by 3 cm., was definitely circumscribed, and was nodular but not infiltrating. The gallbladder and duodenum were normal. The liver was somewhat sclerotic.

The patient withstood the operation well and, except for a moderate degree of postoperative distention, convalescence was uneventful. Ten per cent dextrose in physiologic solution of sodium chloride was given intravenously on the first three days. Blood sugar estimations, made at least twelve hours after such administration, showed that the blood sugar remained at a normal level. Subsequently the oral intake was sufficient, and the patient was soon eating a general diet without additional feedings. The drains were removed on the eighth day. Healing was delayed by a small amount of pancreatic drainage. This rapidly cleared up, leaving a firm scar in a few weeks.
